

**The International Conference on Sustainable Futures:
*Environmental, Technological, Social and Economic Matters***

**May 20-22, 2020
Kryvyi Rih, Ukraine**

Statement of Peer review

In submitting conference proceedings to *Web of Conferences*, the editors of the proceedings certify to the Publisher that

1. They adhere to its **Policy on Publishing Integrity** in order to safeguard good scientific practice in publishing.
2. All articles have been subjected to peer review administered by the proceedings editors.
3. Reviews have been conducted by expert referees, who have been requested to provide unbiased and constructive comments aimed, whenever possible, at improving the work.
4. Proceedings editors have taken all reasonable steps to ensure the quality of the materials they publish and their decision to accept or reject a paper for publication has been based only on the merits of the work and the relevance to the journal.

Title, date and place of the conference

The International Conference on Sustainable Futures: Environmental, Technological, Social and Economic Matters (ICSF 2020)

May 20-22, 2020 | Kryvyi Rih, Ukraine

Proceedings editor(s):

Serhiy Semerikov, Serhii Chukharev,
Serhiy Sakhno, Andrii Striuk,
Viacheslav Osadchy, Victoria Solovieva,

Abstract. This is an introductory text to a collection of papers from the ICSF 2020: The International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters, which held at Kryvyi Rih National University, Kryvyi Rih, Ukraine, on May 20-22, 2020. It consists of an introduction, conference topics review, and some observations about the event and its future.

ICSF 2020 at a glance

The International Conference on Sustainable Futures: Environmental, Technological, Social and Economic Matters (ICSF) is a peer-reviewed international conference, which is the premier interdisciplinary forum for social scientists, life scientists, engineers, and practitioners to present their latest research results, ideas, developments, and applications (Fig. 1).

Fig. 1. ICSF 2020 logo (designed by Dr. Andrii Striuk).

The ICSF occupies contributions in all aspects of sustainable development, focused on the intersection of sustainability, environment and technology, and their more significant implications for a corporation, government, education institutions, regions, and society both at present and in the future.

ICSF has two presentation levels, Pre-conference

Workshops and Main Conference.

Ecochemistry Education for Sustainable Development Workshop

Ecochemistry Education for Sustainable Development Workshop (EcoChemSD-WS'2020) is a peer-reviewed international workshop that occupies contributions in all aspects of environmental chemistry and ecochemistry, ecochemistry education, and modern educational technologies.

EcoChemSD-WS'2020 main topics of interest are:

- ecochemistry research for the sustainable development;
- environmental chemistry for the sustainable development;
- ecochemistry education for the sustainable development;
- modern educational technologies in the chemistry education;
- chemistry teacher's training for the sustainable future.

EcoChemSD-WS'2020 Program Committee chair is Dr. Pavlo Nechypurenko.

Fintech, Greener Economy & Finance Workshop

Science has confirmed that the world is facing an environmental emergency. As it stands, very few countries are on track to meet either their national climate targets or reach the Sustainable Development Goals. It is now clear that we need a radically different approach to governing our economies. A green economy defined as low carbon, resource-efficient, and socially inclusive. In a green economy, growth in employment and income is

* Corresponding author: semerikov@gmail.com

driven by public and private investment into such economic activities, infrastructure, and assets that allow reduced carbon emissions and pollution, enhanced energy and resource efficiency, and prevention of the loss of biodiversity and ecosystem services. New financial technologies (“fintech”) offer the potential to unlock green finance technologies, such as blockchain, the Internet of Things, and Big Data assisting in the transition to a greener economy. By reducing costs and boosting efficiency, fintech mobilizes green finance, enables poorer people to access clean energy through innovative payment systems, and facilitate free savings for rich and poor alike.

The financial markets and the promotion of sustainable finance play a crucial role in mitigating climate change. The topic will address in the Fintech, Greener Economy & Finance Workshop (FGE&F-WS’2020), which aims to provide a forum for different perspectives and ideas to stimulate the debate around sustainable future.

FGE&F-WS’2020 main topics of interest are:

- challenges of the green economy concept and policies in the context of sustainable development, poverty and equity;
- potential opportunities and risks of trade, arising in the transition to the green economy;
- impact of climate change on financial markets, and vice versa;
- means by which financial markets can support sustainable finance;
- significance of digitalisation, financial technology and data for green investments;
- challenges in defining sustainability;
- role of climate change in financial supervision and financial risks;
- blockchain applications for sustainable development;
- blockchain use-cases for renewable energy, decentralized electricity market, carbon credits and climate finance;
- innovation in financial instruments, including green bonds;
- fintech and risks and dangers;
- recommendations to design a sustainable financial and economical system.

FGE&F-WS’2020 Program Committee chairs are Prof. Vladimir Soloviev and Dr. Victoria Solovieva.

Geography Education for Sustainable Development Workshop

Geography Education for Sustainable Development Workshop (GESD-WS’2020) is a peer-reviewed international workshop. During the GESD-WS’2020, the researchers who are committed to the problems of geographic education for sustainable development can present their latest research findings, ideas, developments, and programs.

GESD-WS’2020 main topics of interest are:

- geography education for the sustainable future: methodological foundations;
- pedagogical geoinformation technology: theory and

practice;

- geography teacher’s training for the sustainable future;
- innovative technologies in the school geographic education;
- cartographic territory research in terms of the sustainable future.

GESD-WS’2020 Program Committee chair is Dr. Olga Bondarenko.

Green IT Hub Workshop

Green IT Hub Workshop (GITHub-WS’2020) is a peer-reviewed international Sustainable Computing workshop focusing on advanced research on Sustainable Computing. The workshop occupies contributions in all aspects of sustainable computing, reflecting modern engineering and technological solutions of the information technology era in the sustainable development of society.

GITHub-WS’2020 main topics of interest are:

- sustainable computing;
- software development for a sustainable society;
- information systems and technologies in the society sustainable development;
- cloud technologies and IoT in the society sustainable development.

GITHub-WS’2020 Program Committee chair is Prof. Tetiana Vakaliuk.

ICT in Education and Sustainable Futures Workshop

ICT in Education and Sustainable Futures Workshop (ICT@ESF-WS’2020) is a peer-reviewed international workshop focusing on the efficient application of information and communication technologies in education, research, economics, ecology, and medicine for a sustainable future.

Contributions in all aspects of the sustainable use of ICT in education and science, reflecting modern solutions for the use of ICT in the sustainable development of society, can be submitted. Today, the most important goal is the ability to integrate the efficient application of ICTs in education, update the pedagogical science, and change education for a sustainable future most fully. It is necessary to give educators and researchers the opportunity to better understand the transformation of society through the use of ICT; to promote the development of new educational approaches and the creation of new educational materials using ICT in support of a sustainable future and “new humanism”; to support the exchange of experience and cooperation between teachers, lecturers and researchers in the dissemination of innovative practices in the use of ICT in education and research within the international educational community. It is vital to present the effective application of ICT in reinforcing the four foundations of learning in the 21st century: critical thinking, communication, collaboration, and creativity.

ICT@ESF-WS’2020 main topics of interest are:

- ICT in secondary education for a sustainable future society;

- ICT in higher education for a sustainable future society;
- ICT in research for a sustainable future;
- supporting the development of 21st century skills through ICT;
- integration of ICT into the economy of a sustainable development society;
- ICT in solving environmental problems of sustainable development.

ICT@ESF-WS'2020 Program Committee chair is Prof. Viacheslav Osadchyi.

Main Conference

Main Conference presentations are grouped into 13 tracks:

1. Sustainable Environment and Environmental Management [1-13].
2. Geotechnical and Geoenvironmental Engineering [14-23].
3. Sustainable Mining [24-31].
4. Sustainable Energy [32-38].
5. Sustainable Computing [39-45].
6. Sustainable Materials and Technologies [46-57].
7. Sustainable Transport [58-62].
8. Sustainable Building and Architecture [63, 64].
9. Sustainable Cities and Society [65-69].
10. Sustainable Education [70-105].
11. Measuring, Forecasting and Monitoring Sustainability [106-108].
12. Corporate Sustainability and Corporate Social Responsibility [109, 110].
13. Sustainable Economy [111-141].

This volume contains the papers presented at ICSF 2020: The International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters held on May 20-22, 2020 in Kryvyi

Rih, Ukraine.

There were 285 submissions. Each submission was reviewed by at least 3, and on the average 3.5, program committee members. The committee decided to accept 141 papers.

ICSF 2020 venue

Kryvyi Rih National University has almost 100-year experience in training generations of specialists (Fig. 2). It is one of the most prestigious higher educational institutions in Ukraine as well as the powerful regional center of Higher Education, science and culture.

Over 100 thousand students from 70 countries all over the world have trained in the university. Currently, the friendly university family includes more than eleven and a half thousand young people getting an education in over forty majors in full and part-time modes of study. Fruitful cooperation with partner universities abroad and integration of the participatory research results in the teaching process facilitate the university's internationally competitive level of education. The university scientists carry out a significant amount of research and design studies in the most urgent evolution directions and tendencies of industrial and social branches in Ukraine and other countries.

The mission of Kryvyi Rih National University is to contribute to the development of society employing competitive specialists training as well as inspiring a new generation of healthy and creative patriotic youth. Guiding principles for sustainable university development are multiplying achievements in science, education, culture, and continuing the proud traditions fostered by dynasties of scientists, professors and researchers. The constant development of the university makes sustainable ground for its promising prospects [142].

Fig. 2. Kryvyi Rih National University main building.

ICSF 2020 program committee

Assoc. Prof. **Leon Abdillah**, Associate Professor of Computer Science, Department of Information Systems, Universitas Bina Darma, Palembang, Indonesia

Leon Abdillah, born in 1978, studied Information Systems, Information Systems Management, and Information Retrieval Systems. Since 2001, he has been working in the field of Information Systems (Computer Science) at the Universitas Bina Darma, where he is currently an associate professor. His research interests include knowledge management systems, e-learning, social media, human-computer interaction, user experience, programming, database, financial technology (FinTech), and IT-based education. He has published a number of papers in international journals, conferences, seminars, books, etc. He also served for several editorial/reviewer boards for some reputable international journals. He won many awards as the best computer science lecturer, best reference paper, excellent paper, and top reviewer from Publons. He also invited speakers for some workshops related to scientific writing, research proposal, and journal/conference management, etc.

E-mail: leon.abdillah@yahoo.com

Dr. **George Abuselidze**, Professor of Economics and Business, Department of Finance, Banking and Insurance, Batumi Shota Rustaveli State University, Batumi, Georgia

George Abuselidze, from the Batumi Shota Rustaveli State University (in 2001) and Ivane Javakhishvili Tbilisi State University, Georgia, in 2005, and a Doctor of Economics Sciences degree (Dr. habil.) from the National Academy of Sciences of Georgia, in 2005. Since 2002, he has been working in the Finance and Banking at the Ivane Javakhishvili Tbilisi State University, since 2006 – Batumi Shota Rustaveli State University where he is currently Head department of Finance, Banking and Insurance. His research interests include Economics, Econometrics, Finance and Social Sciences (miscellaneous). He has published a number of papers in international journals and volumes in book series, is a member of editorial or/and review boards of *Oeconomia Copernicana*, *Journal of Financial Economic Policy*, *International Journal of Economics and Finance*, *Journal of Science and studies of accounting and finance: problems and perspectives*, *Management Studies* and etc. He also played instrumental role in different prestigious internal collaborative research project with USA, Canada, Lithuania, Poland, Ukraine, Turkey and etc.

R. S. Ajin works as a Hazard Analyst (Geology) with the Kerala State Disaster Management Authority (KSDMA), Thiruvananthapuram, India. He has an M.Sc. degree with First rank in Applied Geology from the University of Madras (Chennai, India) in addition to have completed more than 120 online short term courses and attended more than 30 training courses. With six years of research experience, he has presented and published more than 20 research papers and edited/reviewed more than 500 manuscripts for various national and international conferences and journals. An Editorial board member for seven international journals and associated with more than 60 international conferences as a member of Scientific Committee, Technical Program Committee, and Reviewer Committee. He is a member of the Council of Asian Science Editors (CASE) and a life member of more than 10 professional societies which include Indian Society of Remote Sensing (ISRS), Indian Institute of Geomorphologists (IGI), Indian Association of Hydrologists (IAH), Association of Geoscientists for International Development (AGID), among others. The Government of Kerala awarded him

‘Good Service Entry’ for his meritorious service during the 2018 Kerala Floods, and he received a ‘Letter of Appreciation’ from the District Collector & Chairman, District Disaster Management Authority (DDMA), Idukki for his meritorious service during the 2018 Kerala Floods. He is a Certified Publons Academy peer reviewer and mentor. He received the Publons Peer Review Awards 2018 for being in the top 1% of reviewers in the ‘Assorted’ category. His research interests are Disaster risk reduction (mainly flood, landslide, and wildfire risk zone mapping and management), Remote sensing & GIS (Applications in Earth and Environmental Sciences), Hydrogeology, Geomorphology, and Environmental geology.

Dr. **Sarfaraz Alam**, Associate Professor of Department of Geography, Institute of Science, Banaras Hindu University, Varanasi, Uttar Pradesh, India

Area of Specialisation: Geography Education, History of Geography, Social and Political Geography and South Asia

Project/s undertaken as PI/Co-PI: Principal Investigator of the project titled “Status of Geography in School Boards of India: A Comparative Study” sponsored by UGC, New Delhi.

Award/recognitions: Awarded Jawaharlal Nehru Scholarship (2001 – 2002) by Jawaharlal Nehru Memorial Fund for Ph.D. fieldwork in Bangladesh.

E-mail: sarfarazalam05@gmail.com; sarfaraz05@yahoo.co.uk

Ph.D. **Tetiana Alohkina**, Senior Researcher. Leading researcher of section of geology and environmental problems of ore deposits State Scientific Institution “Center for problems of marine geology, geoecology and sedimentary ore formation of the National Academy of Science of Ukraine”, Kryvyi Rih, Ukraine

Tetiana Alohkina, born in 1972, received a Candidate of Biological Science degree (Ph.D.) in 2005. Since 2005, she has been working in the field of hydroecology at the State Scientific Institution “Center for problems of marine geology, geoecology and sedimentary ore formation of the National Academy of Science of Ukraine”, where she is currently in position – leading researcher. Her research interests include assessment of hydroecosystems transformation, rivers revitalization, monitoring of changes in a natural state of the hydrosphere and the lithosphere in the technogenesis conditions. She has published a number of papers in domestic and international journals.

E-mail: Alohkina@gmail.com

Dr. **Dmytro Antoniuk**, Assistant Professor of the Department of Software Engineering, Zhytomyr Polytechnic State University, Zhytomyr, Ukraine

Dmytro Antoniuk, born in 1981, received a Candidate of Pedagogical Sciences degree (Ph.D.) from the Institute of Information Technologies and Learning Tools, Ukraine, in 2018. Since 2003, he has been working in the field of Software Engineering and Information Technologies at the Zhytomyr Polytechnic State University, where he is currently Assistant Professor of the Department of Software Engineering and in the practical field of IT business. His research interests include software engineering, business in IT, computer-based business-simulation, economic and financial literacy of technical professionals. He has published a number of papers and proceedings in the journals and material of conferences.

Prof. Dr. **Vitalina Babenko** is Professor of International E-commerce and Hotel&Restaurant Business Department, V. N. Karazin Kharkiv National University, Ukraine

Vitalina Babenko is Professor (Full), Dr. Sci. (habil.) in Economics, Ph.D. in Technical Sciences. Her sphere of scientific interests includes the management of innovation processes, economic-mathematical modelling, information systems and technologies. She has published around 200 papers in peer-reviewed journals and in the proceedings of conferences. She has taken part in more than 100 conferences and workshops as a Keynote Speaker, member of the Scientific Program Committee, an Organizer and Session Chair. She is Editor-in-Chief of Journal of International Relations, Economics, Country Studies, Tourism (<https://periodicals.karazin.ua/irtb/index>) and member of editorial board of some scientific journals. She is the Member of Doctoral Academic Council in Economics, Expert of the Ministry of Education of Ukraine and Expert of Ukrainian Institute Scientific Technical Information.

Anatoliy Berezovsky, Professor, Doctor of Geological Sciences degree, Department of Department of Geology and Applied Mineralogy, Kryvyi Rih National University, Kryvyi Rih, Ukraine

Anatoliy Berezovsky born in 1966 in the city of Volgograd, Russia, in 1990 graduated from the Kryvyi Rih Mining Institute with a degree in Geology, in 1998 graduated from the National Polytechnic Institute of Lorraine, France with a degree in Geology, in 1994 received a Candidate of Geological and Mineralogical Sciences degree (Dr. phil.) from the Institute of Geological Sciences NAS of Ukraine, in 2010 received a Doctor of Geological Sciences degree (Dr. habil.) from the Institute of Geological Sciences NAS of Ukraine, Corresponding member of Mining Academy of Ukraine. Since 1994, he has been working in Kryvyi Rih National University: since 1994 – as an assistant, since 1998 – an assistant professor, since 2012 – a professor. His research interests include paleontology, stratigraphy, mineralogy and paleogeography. Anatoliy Berezovsky was the author of over 100 scientific papers published in refereed journals and is the editorial boards of the scientific journals: “Bulletin of the University of Dnepropetrovsk. Geology, geography” and “Geology and Mineralogy Bulletin of Kryvyi Rih National University”.

Dr. **Liudmyla Bilousova**, Full Professor of Computer Science Department at H. S. Skovoroda Kharkiv National Pedagogical University, Ukraine

Liudmyla Bilousova got a M.A. in Radio-physics from Kharkiv State University, USSR (1959), and Ph.D. in physical-mathematical science from Kharkiv State University, USSR (1970). Liudmyla Bilousova headed Computer Science Department at G.S. Skovoroda Kharkiv National Pedagogical University for 27 years (1991-2018). She is a founder and a head of her scientific school on the problems of development of Informatics education and the implementation of innovative technologies in educational process. In the framework of the school a series of Ph.D. and doctoral research has been completed. Dr. Liudmyla Bilousova is a scientific supervisor of 21 Ph.D. theses. She is an author of about 400 scientific and methodical works including 1 collective monograph and 64 tutorials. Liudmyla Bilousova is a program committee member of International Conference ICTERI-2019 and International Workshop CTE.

Dr. Olga Bondarenko, Candidate of Pedagogical Sciences, Associate Professor, Department of Economic and Social Geography and Methods of Teaching, Kryvyi Rih State Pedagogical University, Kryvyi Rih, Ukraine

Olga Bondarenko, born in 1979, in 2001 graduated with honors from the geographical faculty of Krivoy Rog State Pedagogical University, majoring in "Pedagogy and Methodology of Secondary Education. Geography and Biology", acquired Bachelor Degree. In 2002 she received a Master Degree with honors in the major "Pedagogy and Methodology of Secondary Education. Geography", qualified as a teacher of geography. In 2009, she successfully defended her Ph.D. thesis at the Republican Higher Educational Institution "Crimean Humanities University" (Yalta) and received a Ph.D. in Pedagogical Sciences. Since 2005 he has been working at Kryvyi Rih State Pedagogical University. Author of a number of scientific publications on vocational education, training of future teachers for pedagogical activity. Her research interests include teacher training, the use of ICTs and GIS technologies in the educational process.

WWW: <https://kdpu.edu.ua/personal/ovbondarenko.html>

E-mail: bondarenko.olga@kdpu.edu.ua

Ph.D. Liudmyla Burman, Associate Professor, Department of Economic and Social Geography and Teaching Methods, Kryvyi Rih State Pedagogical University, Kryvyi Rih, Ukraine

Liudmyla Burman, born in 1970, received her Ph.D. in Pedagogical Sciences (Ph.D.) from Volodymyr Hnatyuk Ternopil National Pedagogical University, Assistant Professor in the Department of Economic and Social Geography and Teaching Methods in 2014. Since 1992 she has been working in the field of economic and social geography and teaching methods at Kryvyi Rih State Pedagogical University. Her research interests include regional geography and social geography of the world, their teaching to students. She has published textbooks and a number of papers in national scientific journals.

E-mail: lburman1989@gmail.com

Dr. Oleksandr Burov, Dr.Sc., Leading Researcher, Institute of Information Technology and Learning Tools, National Academy of Pedagogic Science of Ukraine

Oleksandr Burov, born in 1953. Educational Background: Dr.Sc. (Eng.), 2007, science field "Ergonomics". Ph.D., 1990, science field "Control in biological and medical systems". National Technical University (Kyiv), Applied Mathematic Department, M.Sc. diploma, 1977. Area of professional interests: Cognitive work, intelligence, human factors/ergonomics, psychophysiology of mental activity. Professional expertise: Psychophysiological assessment of human performance, functional state and prediction of operators' fitness for duty and performance (power industry, space, aviation). Field of application: Space, aviation, power industry, education and talent development.

Prof. **Aleksandr Cariow**, Professor of Computer Science, Department of Computer Science and Information Technology, West Pomeranian University of Technology, Szczecin, Poland

Aleksandr Cariow, born in 1954, received the Candidate of Sciences (Ph.D.) and Doctor of Sciences degree (DSc or Habilitation) in Computer Sciences from LITMO of St. Petersburg, Russia in 1984 and 2001, respectively. In September 1999, he joined the faculty of Computer Sciences and Information Technology at the West Pomeranian University of Technology, Szczecin, Poland, where he is currently a professor in the Department of Computer Architectures and Telecommunications. His research interests include computational mathematics, digital signal and image processing algorithms, convolutional neural networks, VLSI architectures, and data processing parallelization.

Prof. **Oleksandr Chernyak**, Kyiv National Economic University named after Vadym Hetman, Kyiv, Ukraine

WWW: http://science.univ.kiev.ua/en/researchgroups/research.php?ELEMENT_ID=2594

Dr. **Serhii Chukharev**, Associate Professor of Department of mining development and mining of National University of Water and Environmental Engineering, Ukraine

Scientific degrees and academic titles: 1990 – Candidate of Technical Sciences; 2015 – Associate Professor of the Department of Underground Mining of Kryvyi Rih National University, Ukraine. More than 50 scientific publications (articles, monographs), including 5 invention. The deputy editor of 8 collective monographs on mining published by the publishing houses of Romania and Bulgaria, deputy chairman of the organizing committee of 5 international conferences. The main directions of scientific activity: mining, underground mining of mineral deposits.

Dr. Giuseppe T. Cirella, Professor of Human Geography, Department of Economics, University of Gdansk, Sopot, Poland

Giuseppe T. Cirella, Dr., received his Ph.D. in Environmental Engineering (Specialization: Sustainability) from Griffith University, Australia. He is the founder of the Polo Centre of Sustainability and is Director and Head of Research. Prior to working for the University of Gdansk, Dr. Cirella held academic positions (Professor) at Saint Petersburg State University, Russia as well as (Research Scientist) at both the Free University of Bozen and Ca' Foscari University of Venice in Italy. He has also held a number of short-term professorships in China (Beijing Forestry University and Inner Mongolia University of Science and Technology), South Africa (University of Pretoria), and Ukraine (International Humanitarian University). He has acted as a principal investigator and coordinator in a number of international projects and is a reviewer and member of the editorial board of several reputed international journals on sustainability and the environment. He has extensive interdisciplinary and cross-cultural experience in socioeconomics as well as expertise in landscape architecture, urban planning, and societal development.

Prof. Dr **Tetiana M. Derkach**, Chair of Professional Education in Technologies and Design, Professor at the Department of Industrial Pharmacy at Kyiv National University of Technologies and Design, Kyiv, Ukraine

Education: Doctor of Science in Education (Habilitation), Institute of Higher Education of the National Academy of Educational Sciences of Ukraine, Kyiv, 2015; Ph.D. in Chemistry, Ukrainian State University of Chemical Technology, Dnipropetrovsk, 2000; MSc with Highest Honours in Physical Chemistry, Faculty of Chemistry, Dnipropetrovsk State University, 1987. Publications/Presentations: Author/co-author of more than 200 publications in refereed journals, conference proceedings and patents. The publication list includes three monographs, seven textbooks, such as textbooks “Inorganic Chemistry for Technologists” (in English), “Information and Communication Technologies in Chemistry Teaching”, etc. Organising committees for a few national/international conferences in chemistry and education. Research interests and hands-on experience in experimental work: development of new experimental techniques in analytical chemistry; application of information and communication technologies in education; formation of chemical competencies in a mixed learning environment.

Dr. **Lubomir Dimitrov**, Professor Mechanical Engineering and Mechatronics, Faculty of Mechanical Engineering, Technical University of Sofia, Bulgaria

Lubomir Dimitrov, born in 1958, received a Ph.D. from the Moscow Technological University (STANKIN), USSR, in 1986. Full time professor at the same (Technical University of Sofia) since 2011. He is head of Mechatronics Laboratory. His main scientific interests are in the area of Mechanical Engineering, Mechatronics, Design of machines and mechanical devices, Design against fatigue, Design and control of industrial systems. The results his researches are published in more than 150 papers in scientific journals and conference proceedings. TU-Sofia vice-principle since 2015, responsible for education, accreditation, and international affairs.

Dr. Viktoriia Dmytrenko, Ph.D., Associated professor, Associated professor of the Department of Oil and Gas Engineering and Technology, National University “Yuri Kondratyuk Poltava Polytechnic”, Poltava, Ukraine

Viktoriia Dmytrenko, born in 1981, received a scientific degree of Candidate of Technical Sciences (Ph.D. in Engineering) (Speciality “Development of Oil and Gas Field”) at Ivano-Frankivsk National Technical University of Oil and Gas (Ukraine) in 2009. Her research interests include reliability enhancement of operation of gas condensate fields in conditions of carbon dioxide corrosion and hydrate formation. She is an author of several utility patents in the field of oil and gas industry. She has published a number of scientific papers in international journals. She is co-author of books “Fundamentals of Oil and Gas Business”, “Chemistry and Research Methods of Raw Stuff and Materials”. She is a member of Technical Committee for Standardization of Ukraine TK 138 “NAFTOGAZ Normalization”, a member of Society of Petroleum Engineering and Society of Drillers of Ukraine.

Dr. Alina Dychko, Professor of Environmental Engineering, Department of Geoengineering, Institute of Energy Saving and Energy Management, National Technical University of Ukraine “Igor Sikorsky Kyiv Polytechnic Institute”, Kyiv, Ukraine

Alina Dychko, born in 1974, received a Candidate of Technical Sciences degree at the National University of Food Technologies, in 2002, and a Doctor of Technical Sciences degree (Dr. Sci., Tech.) at the State Ecological Academy of Postgraduate Education and Management, in 2017. Since 2004, she has been working in the field of environmental safety at Institute of Energy Saving and Energy Management, Igor Sikorsky Kyiv Polytechnic Institute, where she is currently a Vice President on Science. Her research interests include integration of the EU requirements on environmental quality management in Ukraine, system analysis of energy saving technologies for biochemical wastewater treatment, methods of their intensification, and also waste biotransformation into biogas. She has published a number of papers in Scopus and other international journals and volumes in book series.

Prof. **Liliana Horal**, vice-rector of Ivano-Frankivsk National Technical University of Oil and Gas, Ivano-Frankivsk, Ukraine.

Mrs. Liliana Horal is a high-level specialist of economy of enterprises and management of regional development. She has worked out about 20 educational courses of an economy, insurance and innovative development of enterprises (in particular enterprises of oil and gas sector). Candidate of engineering sciences in underground storage of gas (1999), doctor of sciences in an economy and management enterprises (2012). She is the successful leader of postgraduate studies. Seven candidates and one doctoral dissertations have defended under her guidance. Mrs. L. Horal is: a chairman of the Specialized Scientific Board D 20.052.06 (by speciality “Economy and management of enterprises”) in the Ivano-Frankivsk National Technical University of Oil and Gas; a member of editorial board of scientific and production edition “Oil and gas industry of Ukraine”; a member of editorial board of “The Scientific herald of the Ivano-Frankivsk National Technical University of Oil and Gas. Series: Economy and management in oil and gas industry”. She is an expert in the area of local development in industry of the strategic planning of local development of the Ukrainian cities within the framework of project “Partnership for development of cities”, development of strategic plan of cities development (2015-2019); an expert of Scientifically-expert board under the head of the Ivano-Frankivsk Regional Council.

Dr. Andrey Kupin, Doctor of Science, Professor of Computer Science, Computer Systems and Networks department, Kriviy Rih National University, Kryvyi Rih, Ukraine

Andrey Kupin, was born in Slovianskerbsk, Luhansk region, Ukraine, in 1972. He received the engineering degree in robotic systems and complexes from East-Ukrainian State University, in 1994 and the Ph.D. degree in automation from Kryvyi Rih Technical University, in 2001. From 2006 to 2007, he worked as an Associated Professor of the Department of Informatics, Automation and Control Systems. In 2010 he became a doctor of science in automation, professor (2013). Dean of the Faculty of Information Technology (2011-2015). From 2007 he is the Head of the Department of Computer Systems and Networks. He is the author more than 170 articles, and 8 patents. Professor Kupin as a scientific adviser has prepared two Ph.D. His research interests include artificial intelligence, information and integrated automation of technological processes. Prof. A. Kupin teaches such academic courses as: "Computer systems of artificial intelligence", "Computer Systems", "Research work of students" and "Computer Networks and Telecommunications".

Dr. Olena Kuzminska, Associate Professor of Information Technology and Distance Learning Department, National University of Life and Environmental Sciences of Ukraine, Kyiv, Ukraine

Olena Kuzminska, born in 1970, received a Candidate of Pedagogic Sciences degree (Ph.D.) from the National Pedagogical Dragomanov University (Kyiv) in 2008. Since 2008, she has been working at the National University of Life and Environmental Sciences of Ukraine, where she is currently head of Information Technology and Distance Learning Department. She has experience in research and teaching in: design and development of innovative blended and distant e-learning technologies, instructional design; development of programs and organization of trainings for teachers and students on efficient use of information & communicational technologies (ICT) in education and research; use of technologies of inquiry-based and project-based activities and implementation of teamwork approaches as a tool for development of digital competences; transfer and modification of education methods to specialized teaching of research

masters' programs and courses of e-learning management and scholarly communication. She research interests also include design and integration of scholarly communication tools to digital educational environment of university; integration of Microsoft and Google cloud services with e-learning process and postgraduate training. She has published a number of papers in international journals and volumes in book series, is a member of program committee of ICTERI (International Conference on ICT in Research, Education and Industrial Applications).

Dr. Valerii Kyrylovych, Professor of Automatization and Computer-integrated Technologies Department named after prof. B.B. Samotokin, State University Zhytomyr Politechnic, Zhytomyr, Ukraine

Valerii Kyrylovych, born in 1953, received a Candidate of Technical Sciences degree (Dr. phil.) from the Kyiv Polytechnic Institute, USSR, in 1990, and a Doctor of Technical Sciences degree (Dr. habil.) from the National Technical University of Ukraine "Kyiv Polytechnic Institute", Ukraine, in 2015. Since 1979, he has been working in the field of robotics of mechanical assembly technologies at the Zhytomyr Field of Kyiv Polytechnic Institute (State University Zhytomyr Politechnic now), where he is currently professor. His research interests include Automated synthesis of robotized mechanical assembly technologies of engineering and instrument making and Automatization using industrial robots. He has published a number of papers in international journals and volumes in book series. He is a member of editorial boards of Bulgarian Journal for Engineering Design (Sofia, the Republic of Bulgaria), Scientific Bulletin of the Ivano-Frankivsk National University of Oil and Gas (Ivano-Frankivsk, Ukraine), Technical Engineering (Zhytomyr, Ukraine).

Dr. Tetiana Lazareva, Doctor of Pedagogical Sciences, Professor of Food and Chemical Technology Department, Ukrainian Engineering Pedagogics Academy, Kharkiv, Ukraine

Tetiana Lazareva graduated from the National Pharmaceutical University as a process engineer of pharmaceutical enterprises (2002) and Kharkiv state University of food and trade (2012) in the direction of “Food industry and processing of agricultural products” as a process engineer. In 2015 she defended her thesis for the degree of doctor of pedagogical sciences in the specialty “Theory and methodology of vocational training” at the Institute of vocational education of the National Academy of Educational Sciences of Ukraine, Kyiv. She is the author or co-author of more than 280 scientific publications. Her latest publications are devoted to teaching students to create innovative objects of the food industry and functional products. She is a member of editorial boards of “Problems of Engineering Pedagogic Education” (Ukraine).

E-mail: Lazareva_T.A@ukr.net

Dr. Aleksandra Lezgovko, Associate Professor, Department of Financial Engineering, Faculty of Business Management, Vilnius Gediminas Technical University and Director of Insurance and risk management institute in Vilnius, Lithuania

Aleksandra Lezgovko has 24 years of managerial experience both in business and academia (leading research teams in designing applications), received a Ph.D. in Economics degree from the Moscow State Regional University in 2012. During the 14 years of project activities, a total of 29 applications were prepared, including 4 that were related to employment and vocational training. The author of 28 scientific and popular science articles. Her publications also include the book “Fundamentals of Insurance Economics”, textbook “Management of Insurance Services Sales Process”. Since 2016, Aleksandra has been participating in the “Sales of Insurance Products” – project, which is an adult re-qualification initiative.

Prof. **Volodymyr Morkun**, Doctor of Engineering, Professor of the Department of Informatics, Control Systems and Engineering Pedagogy, Vice-Rector for Research, Kryvyi Rih National University, Kryvyi Rih, Ukraine

Volodymyr Morkun was born in 1951, became Candidate of Engineering Sciences in 1984 at Dnipropetrovsk Mining Institute (Ukraine) and Doctor of Engineering at Kryvyi Rih Technical University (Ukraine) in 2000. Since 1975, he has been investigating into automation of control processes, computer sciences and technologies at Kryvyi Rih National University where he is currently Vice-Rector for Research. His research interests involve theoretical substantiation, methods and computerized systems of adaptive control over technological mining processes on the basis of ultrasonic, magnetic and radiomagnetic measurements of ore material characteristics. He is the author of over 400 scientific works in international journals and monographs. He is also the chief editor of Computer Science, Information Technology, Automation and is a member of editorial boards of six scientific editions. Priorities of basic scientific and technical solutions developed by Morkun's research school are defended by patents in the USA, Great Britain, Canada, Germany, France, India and Sweden as well as Ukrainian patents and certificates of authorship.

Dr. Olena Pakhomova, Candidate of Pedagogical Sciences, CELTA teacher, Associate Professor, English Philology Department, Oles Honchar Dnipro National University, Dnipro, Ukraine

Olena Pakhomova, born in 1977, in 1999 she graduated with honors from the Foreign Language Department of Kryvyi Rih State Pedagogical University, majoring in "English and German Languages and Literature". In 2011 she defended her Ph.D. thesis at Volodymyr Vinnychenko Kirovograd State Pedagogical University and received a Ph.D. in Pedagogical Sciences. From 2008 till 2019 she worked at English Language with Methods of Teaching Department of Kryvyi Rih State Pedagogical University. Currently she is an Associate Professor of English Philology Department at Oles Honchar Dnipro National University. Author of a number of scientific publications on vocational education, the theory and method of professional training, her research interests include methods of English teaching, country studies, and the use of ICTs in the educational process.

Dr. Oleksandr Palyvoda, Associate Professor, Department of Industrial, Civil and Urban Construction, Kryvyi Rih National University, Kryvyi Rih, Ukraine

Oleksandr Palyvoda, born in 1987, received a Candidate of Engineering Sciences degree (Ph.D.) from the National Aviation University, Ukraine, in 2016. In 2019 was awarded the title of Associate Professor in the Department of Industrial, Civil and Urban Construction. He has been teaching at Kryvyi Rih National University since 2013. He also has practical experience in the construction industry for about 5 years. His research interests include research, design and implementation of new effective structures, as well as modern methods of repair and reinforcement, waterproofing and chemical protection of building structures. He has published a number of articles in international journals and has presented numerous papers at international conferences.

E-mail: palyvoda87@ukr.net

Dr. Marinela Panayotova, Prof. in Mineral Processing and Recycling (2011), Dept. of Chemistry, University of Mining and Geology (UMG), Sofia, Bulgaria

Assoc Prof. in Physical Chemistry (2001); Ph.D. in Physical Chemistry (1991); M.Sc. Chemistry (Inorganic and Analytical) – 1984; Post-Graduate specialization “Environmental Technology and Management”, equivalent to a British MSc course – 1994. Head of the department of Chemistry at UMG since 2012; Director of the Kardzhali branch of the UMG – 2009-2016. Professional and research interests: Environment protection – processes of mobilization and immobilization of water, soil and air pollutants; Technologies for wastewater and gases purification; Processing of minerals, raw materials (ores, concentrates, liquid and solid waste) – hydrometallurgical, flotation, physicochemical, chemical and electrochemical methods; Nanocomposites; Chemistry of RES; Corrosion and corrosion protection of metals and concrete. Totally patents and utility models – 19. Totally 150 publications, 18 books (monographs, textbooks, teaching aids) – 5 of them in English; 8 invited chapters in English. Totally 44 projects and 8 EIA. Member of the EGRC, ECE, UN – 5-th, 6-th and 8-th sessions. Inventor of the year – Chemistry and Environment – 2014, Bulgaria.

Dr. Liubov Panchenko, Professor at the Department of Sociology, National Technical University of Ukraine “Igor Sikorsky Kyiv Polytechnic Institute”, Kyiv, Ukraine

Liubov Panchenko was awarded a Candidate of Pedagogical Sciences degree (Dr. phil.) from H. S. Skovoroda Kharkiv National Pedagogical University, Kharkiv, Ukraine, in 1995, and a Doctor of Pedagogical Sciences degree (Dr. habil.) from the Luhansk Taras Shevchenko National University, in 2012. Since 1993, she has been working in the field of information and communication technology in education. Since 2016 she has been a Professor at the Department of Sociology, National Technical University of Ukraine “Igor Sikorsky Kyiv Polytechnic Institute”. Her research interests include information and communication technology in education, university’s educational environment, MOOCs, data analysis and multivariate methods in scientific research, digital storytelling, adult education. She has published a number of papers and text books (“Computer data analysis”, “Data analysis practicum”) and is an editorial board member of the Ukrainian journals “Information Technologies and Learning Tools” (associated editor), “e-Environment of Modern University”, and “Humanization of the educational process”.

Dr. **Alexander Podolyak**, Candidate of Agricultural Sciences, Associate professor. Director of the Gomel Regional Station for Chemization of Agriculture, Gomel, Republic of Belarus

A. Podolak, born in 1968, received a Ph.D. after successfully defending his Ph.D. thesis on agrochemicals at the Belarusian Research Institute of Soil Science and Agrochemicals in 2002. In 2003 he headed the Gomel Territorial Department of Agricultural Radiology and Agroecology of the Institute of Soil Science and Agrochemicals. In 2005 he was awarded the academic title of associate professor in the specialty – ecology. From 2008 to 2018 he worked as Deputy Director for Scientific Work of the Republican Research Enterprise “Institute of Radiology” of the Ministry of Emergency Situations of the Republic of Belarus. His research interests relate to the behavior of radionuclides and heavy metals in the soil-plant system. He co-authored eight monographs and more than 200 scientific articles in domestic and foreign publications. Since 2020 he has been a Doctor of Agricultural Sciences at the Department of Agricultural Chemistry of the Belarusian State Agricultural Academy.

Dr. **Vasyl Porokhnya**, Doctor of Economic Sciences, Doctor of Technical Sciences, Professor, Professor of Department of Economic of Classic Private University, Zaporizhzhia, Ukraine

Vasyl Porokhnya, born in 1949. Doctor of Technical Sciences – 1993 and Doctor of Economic Sciences – 2004. In 2004 he received an internship in the USA and received a certificate in on-line technologies in education. Since 2005 he has been implementing the theory of intellectual capital development in the educational sector and applying it in the branches of production based on the strategy of development of the human potential of the state. The works have been tested in Moscow (Institute of Management Problems of the Russian Academy of Sciences, Moscow State University), St. Petersburg (CEMI RAN), Poland, Chicago, Spain and the annual All-Ukrainian Scientific and Methodological Conferences “Problems of Economic Cybernetics”. As a result of research on the innovative development of intellectual capital at the micro and macro levels, he trained seven doctors of science.

E-mail: vprrnp76@gmail.com

Dr. Valerii Pozdniakov, Ph.D. (Engineering), Senior Lecturer, Senior Lecturer of the Department of Industrial Engineering and Maintenance of Gamal Abdel Nasser University of Conakry (UGANC), Guinea

Valerii Pozdniakov was born in 1949, defended his thesis in 1979 at Donetsk National Technical University (Ukraine) in the field of mining machines and complexes, worked at this University in the departments first “Mining machines” and then “Technology of Mining Engineering”. Senior Lecturer since 1981. In 1984-85, he worked at the Ostrava Higher School of Mines (Czechoslovakia), and in 1989-94, he worked as a Senior Lecturer at the Tebessin National University (Algeria). Since 1996, he has been working as an Senior Lecturer in the Republic of Guinea (Conakry). Until 2010, in the Mining Department of the Mining and Geological Institute of Boke, and now in the Department of Industrial Engineering and Maintenance of UGANC (Conakry). His research interests include the theory of operation and operation of industrial equipment, as well as its maintenance. He has many international publications, participated in collective monographs.

E-mail: valerypoz49@gmail.com

Dr. Svitlana Pozdniakova, Ph.D. (Economics), Senior Lecturer, leading specialist of the Department of Reforms of the Prosecutor General’s Office of Ukraine, Ukraine

Svitlana Pozdniakova was born in 1981. She defended her thesis in 2009 at the Institute of Economic and legal research of the National Academy of Sciences of Ukraine. Initially, she worked as an assistant, and from 2009 to 2015 as a Senior Lecturer at the Department of Personnel Management and Labor Economics of Donetsk National Technical University (Ukraine). In 2015, she was invited to work in the Department of Reforms of the Prosecutor General’s Office of Ukraine. Research interests are related to the issues of personnel management of enterprises, namely, the development of a competency model for employees of the enterprise; conformity assessment of competences of employees with the requirements of the position; the definition of programmes for the development of the missing competencies; conformity assessment of competencies of candidates to the position of its requirements. She has many scientific articles in specialized Ukrainian and international publications, published a monograph “Assessment of human capital accumulation in industrial enterprises”. She took an active part in the TEMPUS CD-JEP 27238-2006 program.

Ph.D. (Tech.) **Serhiy Sakhno**, Associate Professor of the Department of Civil Engineering of Kryvyi Rih National University, Kryvyi Rih, Ukraine

Serhiy Sakhno was born in 1958, has degrees as a Civil engineer, Economist, Master of Intellectual Property, Specialist of Mechanical and Machine Engineering. Received degrees of the Candidate of Technical Sciences (Ph.D.) from the Kyiv Civil Engineering Institute in 1992. Has more than 50 scientific publications (articles, proceedings, monographs), including four patents for invention. His areas of scientific interest: cement activity research, extending the life of structures that have developed their resource, study of the effects of dynamic factors on the reliability and durability of mechanisms and structures.

E-mail: budfac@gmail.com

Prof. **Oleksandr Samorodov**, Doctor of Technical Sciences (D.Sc.), Head of the Department of Geotechnics, Underground and Hydrotechnical Structures, Kharkiv National University of Civil Engineering and Architecture, Kharkiv, Ukraine.

More than 100 scientific publications (articles, proceedings, monographs), including 10 patents for invention; the supervisor of 6 post-graduate students, 5 of whom have defended their candidate's dissertations and hold the degree of Candidate of Technical Sciences (Ph.D.). Primary areas of research activity: research of the behaviour of combined pile-raft foundations (CPRF) of multi-storey buildings and structures: load-bearing capacity, compressible thickness and mechanical parameters of soil bases, simulation parameters of the base – foundation system with the use of different soil base models; research of the pile – soil mass system under various combinations of loads on the pile and deformations of the mass; research of soil pressure on retaining walls and underground facilities such as caissons, particularly in case of local loads on the surface; research of the interaction with foundation bases with cutouts in the bottom subject to significant moment loads.

Dr. Oleg Spirin, Doctor of Pedagogy, Full Professor, Corresponding Member of the National Academy of Pedagogical Science of Ukraine, Vice Rector for Research and Digitalization of the University of Educational Management, Kyiv, Ukraine

Oleg Spirin, born in 1965, 1989 – graduated from Zhytomyr Ivan Franko State University, Ukraine, majoring in Mathematics and Physics. Scientific degree: Ph.D (2002), Thesis “Differentiated approach to the Study of the Foundations of Artificial Intelligence in Computer Science Course Physics and Mathematics in Higher Educational Institutions”; Doctor of Pedagogical Sciences (2009), Thesis “Theoretical and Methodological Basis of Credit-modular System of Future Teachers of Informatics Training”. Academic status: Associate Professor of Computer Science (2004). Professor of the specialty 13.00.10 – Information Technologies in Education (2013). Prof. Spirin is an expert in the informatization of education and science and information training of students. He has published a number of papers in international journals and volumes in book series, is Deputy Editor-in-Chief of Electronic scientific edition “Information Technologies and Learning Tools”, member of the Editorial Boards of the specialized journals “Information Technologies in Education”, “Computer in School and Family”.

Dr. Tetiana Starova, Associate Professor, Head of Department of Chemistry and Methods of its Teaching, Faculty of Natural Sciences, Kryvyi Rih State Pedagogical University, Kryvyi Rih, Ukraine

Tetiana Starova, born in 1980, received a Candidate of Chemical Sciences degree (Ph.D.) from the Oles Honchar Dnipro National University, Ukraine, in 2009. Since 2007, she has been working in the field of Analytical Chemistry and Ecological Chemistry at the Kryvyi Rih State Pedagogical University, where she is currently Head of the Department of Chemistry and Methods of its Teaching. Her research interests include methods of environmental objects’ analysis and ecological chemistry issues. She has published a number of papers in scientific journals.

E-mail: simaneneko@ukr.net; t.starova@kdpu.edu.ua

Dr. Andrii Striuk, Ph.D., Head of Simulation and Software Engineering department of Kryvyi Rih National University, Kryvyi Rih, Ukraine

Andrii Striuk, born in 1979. In 2000 he graduated from the Kryvyi Rih Technical University with a degree in Automated Systems Software. In 2001, he received a master's degree in computer science. Has been working at the Department of Modeling and Software of Kryvyi Rih National University since 2000. Combines educational activities with practical, developing and implementing educational software products. In 2011 he defended his Ph.D. thesis. From 2014 to 2017 he is studying at the doctoral program in Institute of Information Technologies and Learning Tools of the NAES of Ukraine (Kyiv, Ukraine). In 2017, he was awarded the Prize of the President of Ukraine for young scientists. Heads the Simulation and Software Engineering department of Kryvyi Rih National University since 2018. Field of scientific interest: professional training of software engineers, mobile learning technologies, the use of augmented reality technologies in education.

Prof. **Mykola Surianinov**, Doctor of Technical Sciences, Professor, Head of the Department of Structural Mechanics, Odessa State Academy of Civil Engineering and Architecture, Odessa, Ukraine

Mykola Surianinov, born in 1956, received a Candidate of Technical Sciences degree from the Moscow Civil Engineering Institute, USSR, in 1985, and a Doctor of Technical Sciences degree in Ukraine. The author of 40 textbooks and monographs, as well as 300 scientific articles. Research interests include numerical methods for structural analysis, methods for calculating composite materials. Supervises two research topics: "Development of the numerical-analytical method of boundary elements to modeling and development of shear, plate and shell constructions" and "Analytical, computer and experimental construction of steel constructions". Member of the editorial board of three scientific journals.

Dr. **Svitlana Sysoieva**, Doctor of Pedagogical Sciences, Professor, Academician-Secretary of the Department of General Pedagogy and Philosophy of Education, National Academy of Educational Sciences of Ukraine, Kyiv, Ukraine

Specialist in the theory and methodology of vocational education, educology, comparative professional pedagogy. Author of the concept of pedagogical creativity in Ukraine, methodology of interdisciplinary research in education. Has formed a scientific school to study the problems of continuing vocational education. Has trained 21 EdD and 47 Ph.D. in Education. Author of more than

470 scientific works. Including: monographs: “Creative development of professionals in terms of magistracy”, “Pedagogical creativity”, “Teacher education for developing creative students”, “Problems of continuing professional education: a thesaurus of scientific research”, “Education and personality in the post-industrial world”; course-books: “Fundamentals of pedagogical creativity”, “Pedagogy and psychology”, “Methodology of scientific and pedagogical research”; manuals: “Essays on the history of pedagogical thought development”, “Interactive technologies of adult learning”, “Theory and practice of higher education”, “Development of research competence of teachers of higher education”; textbook “Educology”; educational programs for Master, Ph.D. students in education and education experts. Editor-in-chief of the scientific journals Continuing Professional Education: Theory and Practice, Pedagogical Process: Theory and Practice, co-editor of the scientific journals Education, The Modern Higher Education Review, Deputy Editor-in-Chief of the scientific journal Educational Discourse, member of the editorial board of the scientific journals *Ruch pedagogiczny* and *Edukacja otwarta*.

Prof. Radomir Timchenko, D. Sc., Professor of Department of Industrial, Civil and Urban Construction, Kryvyi Rih National University, Kryvyi Rih, Ukraine

Radomir Timchenko, was born in 1959, received his Doctor of Science degree in 2009. Since 1990 he has been working in the field of architecture and urban planning at Kryvyi Rih National University. His research interests include the calculation and design of buildings and structures in complex engineering-geological conditions, including the implementation of numerical methods; engineering preparation and design of urban and disturbed territories. In this field, as well as on architecture and urban planning, more than 350 publications have been prepared, more than 40 patents of Ukraine have been obtained. He is a member of the specialized scientific council for the defense of doctoral and Ph.D. theses, as well as a member of the editorial board of the professional scientific and technical collection of articles “Urban planning and territorial planning”. He is a member of the All-Ukrainian and International Associations of Soil Mechanics, Geotechnics and Foundation (ISSMGE).

Ph.D.Eng. Mihaela Toderas, Surveying and Underground Constructions Department, Faculty of Mines, Mining Engineering, University of Petroșani, Romania

Mihaela Toderas, Professor in the field of Underground Mining Constructions, Faculty of Mines, Ph.D. supervisor in Mines, Oil and Gas (Dr. habil.) from the University of Petroșani, Romania, in 2016. From May, 2016 to present vice-dean of the Faculty of Mines. Since 1997 is Expert Engineer in Technical, Economic and Management of Mining Companies, title obtained after graduating National Polytechnic Institute of Lorraine, Nancy – France. She attends to the problems of underground and quarries mineral resources exploitation, stability and reliability of underground works mining, both theoretically and practically; author of several books and papers published in international scientific journals, as well national and international conferences. The topics addressed in the research activity are varied. The scientific research activity has focused particularly on geomechanics, rock mechanics and rock rheology issues and underground constructions; is a reviewer member of Journal of Geological Resource and Engineering, reviewer on honorary basis of GJSFR USA, reviewer and member of scientific committee of different international conferences.

E-mail: toderasmihaela@yahoo.com

Ph.D. Krzysztof Tomiczek, lecturer at the Faculty of Mining, Safety Engineering and Industrial Automation at the Silesian University of Technology, Silesian University of Technology in Gliwice, Poland

Since 1998, he has worked professionally at the Faculty of Mining, Safety Engineering and Industrial Automation at the Silesian University of Technology in Gliwice. In 2007 he was awarded with honors the title of doctor of technical sciences in the field of mining and engineering geology in the specialty of rock and rock mass mechanics. Between 1998 and 2008 he was particularly associated with the Laboratory of Rock Mechanics (head professor Marek Kwaśniewski, president of the Polish group of the International Society of Rock Mechanics). Participant at the theory of plasticity and elasticity courses at the Institute of Fundamental Technological Research of the Polish Academy of Sciences in Warsaw (IPPT PAN, Prof. Michał Kleiber, Prof. Zenon Mróz, Prof. Wiktor Gambin). Twice awarded the second degree prize of the Rector of the Silesian University of Technology. Participant of short-term internships / scientific courses, among others in: Germany (Itasca C.G.), Switzerland (Friedli Geotechnik AG Zürich, ETH Zürich), Italy (CISM, Udine), Czech Republic (GF Instruments, s.r.o.) and South Africa (JTC Ltd., MINCO mineral mining operation). He specializes in geomechanics, rock mechanics, geotechnics and soil

mechanics, including in laboratory tests of rock and granular material properties, numerical modeling of rock mass behaviour and simulations of laboratory tests. Author of several dozen articles and papers.

Dr. **Richard Tomlins**, Assistant Professor, International Centre for Transformational Entrepreneurship (ICTE), Faculty of Business & Law, Coventry University, Coventry, England.

Richard received his Ph.D. by research in Ethnic Relations in 1997 from the University of Warwick. He has been Professor of Race, Diversity and Housing at Leicester De Montfort University, and Visiting Professor of Race and Diversity at Coventry University whilst directing his own consultancy Cohesia. His new innovative research techniques and approaches are demonstrated by recent project awards: £1,349,961.58 3 year ESRC Global Challenges' Research Fund on playful educational models for social resilience (Co-I); Playfulness and creative economy work informing a £450,000 Coventry City of Culture Trust transforming leadership win (Co-I); 84,272.00 USD for an 18 month UNESCO International Fund for Cultural Diversity project, one of only 9 projects awarded globally (Co-I); £197,415.00 2 year Newton Impact Fund "Reducing social and economic inequalities through creative economy and social entrepreneurial interventions in Mexico". This is British Council recognition of the innovation in his previous Sprint rapid prototyping forming part of nested playful techniques flowing from LEGO through Business Model Canvas and Sprint to Nudge (PI). These are also showcased in his 3 related Ukraine projects totalling £100,000 with Oksana Malynka and other colleagues from the Ivano-Frankivsk National Technical University of Oil and Gas (PI). Richard is active in the creative economy in Coventry participating in the writing of its successful bid to be UK City of Culture for 2021 and working locally with Fargo Creative Village to scale its offer.

Dr. **Nataliia Valko**, Ph.D. of Physics and Mathematic Sciences, Department of Informatics, Software Engineering and Economic Cybernetics, Kherson State University, Kherson, Ukraine

Nataliia Valko, in 2006 earned a Ph.D. degree of Physics and Mathematic Sciences in specialty «Mathematical modeling and numerical methods». She has extensive experience in teachers' education via modern teaching technologies, blended learning, STEM-education. Her teaching experience in University is over 20 years. She is one of the organizers of the STEM school of KSU. She has management skills in the field of teacher training, planning educational activities, creating distance learning courses on the Moodle platform. She manages students design work to create models of robotic systems. Effectively applies innovative teaching methods for future teachers of natural-mathematical disciplines using robotics and their preparation for using STEM-technologies in teaching. She actively studies innovative teaching methods, methods of project activity. She has published a number of papers of different kinds (including books, articles in

scientific international journals, conference proceedings etc.), is a member of editorial boards of Journal of Information Technologies in Education (ITE).

Dr. **Fengwei (David) Xie**, University of Warwick, Coventry, England

Dr. Fengwei (David) Xie holds a BE degree (2004) in Biological Engineering and a Ph.D. degree (2009) in Polysaccharide Engineering from South China University of Technology (China). Since 2018, he has had research experiences at multiple institutions such as University of Guelph (Canada), University of Queensland (Australia), Université de Strasbourg (France), University of Warwick (UK) and California Institute of Technology (USA). He is currently a Marie Skłodowska-Curie Individual Fellow at University of Warwick (UK). His research focuses on ‘green’/bio-polymers for sustainability, environmental protection, people’s better life and health. He works on developing ‘green’ processes and ‘green’ materials for greater resource efficiency and reduction in

wastes and carbon footprints. He is particularly interested in the use of renewable, biomass resources for materials development. He also studies the functionality of biopolymers and polysaccharides as food ingredients. He investigates the mechanisms behind the relationship among processing, structure and properties/functionality of biopolymers and biocomposites, leading to advantageous materials and nutritious food. His research has led to over 100 referee journal publications. He is a Member of the Royal Society of Chemistry.

How coronavirus is shaping sustainable development

“The world is changed. I feel it in the water. I feel it in the earth. I smell it in the air. Much that once was is lost, for none now live who remember it.” [143]

The rapid spread of the coronavirus that causes COVID-19 has change conference organization. In Ukraine, the Ministry of Healthcare is advising people to prepared for disruptions to daily life that will be necessary if the coronavirus spreads within communities. On March 11, 2020, the Cabinet of Ministers of Ukraine introduced a three-week nationwide quarantine in connection with a pandemic, and all public events in the country have been canceled [144]. Three weeks ago, we still believed that the outbreak impact would not be global [145].

“Conferencing world from the past now seems surreal, like science fiction, though the world around us looks like science fiction too” [146]. As the conference organizers, in the current crisis we had to make a rational decision regarding the paper presentations: a) cancel this year conference and put presentations online; b) postpone the conference to an indefinite time in the vague future; c) change dates to Fall 2020; d) merge conferences of this

and next year; e) allow the mixed participation, both real and virtual.

It seems the last choice is safe and rational, so we decided not to change ICSF dates and give to participants the possibility to make a real presentation using ICT augmentation.

The coronavirus pandemic is now affecting practically every country on the planet. The quarantine restrictions put in place by the governments have a lot of serious socio-economic, technological and environmental effects. Could the coronavirus outbreak be sustainability’s big break?

Peter Bakker, the President of World Business Council for Sustainable Development (WBCSD), emphasis that most governments are now first and foremost focused on slowing down the spreading of the disease and shoring up medical support systems to aid those who fall seriously ill: “For business, it is an equally pivotal moment to deploy all its care, critical know-how, reach and resources. Businesses everywhere are looking after their employees and creating contingency plans to map the risks in their operations” [147]. The WBCSD has started sharing examples of positive business leadership during these challenging times: how business demonstrating their responsibility towards society.

WBCSD has set up a COVID-19 Response Program. WBCSD's call to action to leverage our combined business expertise centered on three areas and focused projects:

- Vital Supply Chains (with a focus on short-term supply chain resilience plan, starting with the food system);
- Return to "Normal" Scenarios (with a focus on employee health and business recovery);
- Long-term Impacts (with a focus on COVID-19 vulnerabilities revealed by the crisis and lessons for future resilience and stakeholder capitalism).

Kevin Moss mentioned that COVID-19 crisis could be a turning point for business: "Right now, businesses are responding to the call to take a socially responsible, purpose-driven and publicly accountable approach to all stakeholders – employees, suppliers and communities – in addition to shareholders. It may seem inappropriate to be thinking of longer-term sustainability in these times of emergency, but the lens through which we are forced to take urgent action right now is the one business leaders can use to ensure the rush to resolve one emergency does not accelerate the onset of another. Let this be the beginning, not the peak, of a corporate transformation journey, so that once society is beyond the immediate threats, we move into a refreshed approach to capitalism" [148].

This crisis offers three opportunities for businesses that want to expand their mandates to lead to a more sustainable future [148]:

1. *Change business models from a linear to a circular economy*: instead of coming out of the crisis by doubling down on pre-crisis consumption patterns and business models, the crisis presents the opportunity to switch from selling more stuff to more people to providing services, reselling previously owned products and creating.

2. *Emphasize the social in the environmental, social and corporate governance*: if ever there was a time for companies to demonstrate their commitment to the health, safety and prosperity of all stakeholders by addressing inequality in the business model, it is now.

3. *Invest in supply chains*: as the Science Based Targets Network notes in its call to action for companies, businesses must prioritize mapping "value chain and assess the risk to freshwater, biodiversity, ecosystems and oceans in major impact locations" [149].

So, COVID-19 has tested the preparedness and resiliency of businesses in terms of their ability to respond to a systemic global shock. Some business responses to the current situation highlight future corporate sustainability opportunities [150].

The UN Secretary-General António Guterres has announced the establishment of the COVID-19 Response and Recovery Fund and launched a report serving as a call to action [151]. Guterres said the recovery from the COVID-19 crisis must "lead to a different economy" – more equal, inclusive and sustainable, to be more resilient to pandemics, climate change, and other global challenges.

The Fund has three aims, with a finance window for each one: stop transmission of the virus, protect the most vulnerable from its socio-economic impacts, and make countries more resilient to future health crises. Window 1,

"Enable governments and communities to tackle the emergency", will support countries to fully implement their National Action Plans for Health Security, helping them close gaps in acquiring essential equipment and supplies, and pay health and social workers.

Window 2, "Reduce social impact and promote economic response", will support immediate social protection measures including cash transfers and food security. It will enable school meal programs and learning to meet children's food and educational needs while boosting digital innovations to support employment, livelihoods, and social services.

Window 3, "Recover better", focuses on national preparedness measures such as maintenance of key services and workforces during crises, and laboratory capacity. This window will also invest in innovative delivery of public services to "achieve sustainable and inclusive economies that leave no-one behind and safeguard country SDG programs from COVID-19-related setbacks".

The UN report on social and economic impacts of the virus outbreak entitled "Shared responsibility, global solidarity: Responding to the socio-economic impacts of COVID-19" [152] is a call to action for the same sets of action prioritized by the Fund. Guterres highlighted the importance of focusing on the people most affected socially and economically by the pandemic: women, older persons, youth, low-wage workers, small and medium enterprises, the informal sector, and vulnerable groups, especially those in humanitarian and conflict settings. He said a multilateral response of about 10% of global GDP will be needed, and that we must prioritize debt alleviation.

Looking longer-term, Guterres said, "when we get past this crisis ... we will face a choice. We can go back to the world as it was before or deal decisively with those issues that make us all unnecessarily vulnerable to crises".

Pointing to the 2030 Agenda and its 17 Sustainable Development Goals (SDGs) as "our roadmap," he said the recovery from the COVID-19 crisis must "lead to a different economy" – more equal, inclusive and sustainable, to be more resilient to pandemics, climate change, and other global challenges.

The COVID-19 Response and Recovery Fund and Call to Action report take a long-term view, stressing that the world must address the issues that "make us all unnecessarily vulnerable to crises", with the 2030 Agenda serving as the roadmap to achieving this (Fig. 3). The Fund seeks to stop transmission of the virus, protect the most vulnerable from its socio-economic impacts, and make countries more resilient to future health crises.

The United Nations commits to working in all countries around the following recommendations [152]:

1. Act decisively and early to prevent the further spread or quickly suppress the transmission of COVID-19 and save lives.

2. Urgently strengthen the resilience of health systems.

3. Provide urgent support to developing countries with weaker health systems.

4. Remove obstacles and allow free and immediate access to research results and ensure that vaccines and

medicines are accessible to all.

5. The United Nations calls on all businesses and corporations to take three primary actions: adhere to health, safety guidelines and provide economic cushions to workers, including through ensuring worker safety and

social distancing and secure wages for those working from home; provide financial and technical support to governments by contributing to the COVID-19 Solidarity Response Fund; repurpose their facilities and business plans to focus on meeting the needs of this crisis.

Fig. 3. COVID-19 affecting all 17 SDGs [152, p. 12].

Conclusion

The vision of the ICSF 2020 is to create a leading interdisciplinary platform for researchers, practitioners and educators, to present and discuss the most recent innovations, trends, and concerns as well as practical challenges encountered and solutions adopted in the fields of sustainability.

The conference is a successfully performing forum for transferring and discussing research results among the academics, students, teachers, government, private sector, or industries. Participants and presenters from several countries such as Australia, Azerbaijan, Belarus, Bulgaria, Czechia, Egypt, Estonia, Georgia, Germany, Guinea, Indonesia, India, Israel, Italy, Kazakhstan, Kuwait, Lithuania, Netherlands, Nigeria, Norway, Poland, Romania, Russia, Saudi Arabia, Serbia, Sweden, Turkey, Ukraine, United Kingdom, United States, Uzbekistan, and Viet Nam have a conference experience to share their significant contribution in the research of the environmental, technological, social and economic issues of sustainable future.

We are thankful to all the authors who submitted papers and the delegates for their participation and their interest in ICSF as a platform to share their ideas and innovation. Also, we are also thankful to all the program committee members for providing continuous guidance and efforts taken by peer reviewers contributed to improving the quality of papers provided constructive critical comments, improvements and corrections to the authors are gratefully appreciated for their contribution to the success of the conference. Moreover, we would like to thank the developers and other professional staff of EasyChair, who made it possible for us to use the resources of this excellent and comprehensive conference management system, from the call of papers and inviting reviewers, to handling paper submissions, communicating with the authors, and creating the conference proceedings.

We are looking forward to excellent presentations and fruitful discussions, which will broaden our professional horizons. We hope all participants enjoy this conference and meet again in more friendly, hilarious, and happiness of further ICSF 2021.

⁴National Aviation University, Kyiv, Ukraine

Abstract. It is necessary to follow signed documents on development of renewable energy, modernization of fuel and energy sector enterprises and waste management in order to fulfil Ukraine's commitments to the global community on climate change prevention. Therefore, it is an urgent task to develop software that allows to solve problems of visual analysis of environmental status dynamics of territorial systems and to determine boundaries of individual territories stability. The authors propose new forms of monitoring data presentation of technogenic loadings and risks which reflect dynamics of environmental situation in the space of informative features. It is important to improve skills of professionals, particularly, stuff of the ministries, enterprises and organizations responsible for decision-making to reduce negative impact on environment and to train future professionals in this area. Curriculums of higher education institutions do not pay much attention on usage of software to support managerial decision-making to reduce negative impact on the environment. It is proposed to improve qualification of such specialists, responsible for management in the following areas: conducting training seminars at the ministries, institutions and departments interested in the implementation of developed systems; scientific and methodological support and advisory assistance in the process of implementation of the software; development and improvement of educational and methodological support for postgraduate students and trainees of advanced training, specialists responsible for decision - making in energy, environmental and related fields.

1 Introduction

A report of the World Commission on Environment and Development "Our Common Future" defines sustainable development as "development that meets needs of modern times without sacrificing future generations to meet their own needs" [1]. From an environmental point of view sustainable development must ensure integrity and viability of natural systems, possibility of self-healing and adaptation to change. In particular, the study of the relationship between environmental and economic components of sustainable development processes requires clarification of limit levels of technogenic loads and to determine the stability limits of urban territorial systems to technogenic impacts.

At this stage, approaches to sustainable development research can be divided into two directions. The first direction is dominant at the global and regional level (top view, i.e. comparative analysis of situation in different countries or regions). These studies aimed to calculate sustainable development indicators and indices according to the methods proposed by the UN Commission and international councils [2-5]. The next

one should include work aimed to identify the stability of individual processes occurring in specific environmental or social systems [6-8]. Only real examples of dynamics analysis of individual systems can reveal dependence on trajectory development (or transition to critical state) of this system on values of the mentioned or other parameters.

Special attention should be given to the development and modernization of monitoring system of ecological status of territorial systems at different levels; to create universal information and monitoring software for monitoring tasks, improving tools of forecasting critical situations and to make necessary management decisions. It should be done for practical implementation of the principles of sustainable development in Ukraine. Development of modern information and computer technologies are focused on the storage, accumulation, systematization and integration of information obtained from various sources, including local level of data analysis and visual interpretation capabilities based on GIS technologies are among the top priorities that is evidenced by the accepted concept [9]. Its implementation should ensure compliance with

* Corresponding author: iatsyshyn.andriy@gmail.com

international commitments in the field of environmental protection, rational use, renewal and protection of natural resources.

Therefore, we consider two aspects important for the research: improvement of monitoring system to forecast and managerial tasks to ensure environmental safety based on information technologies; professional development of specialists in the energy, environmental and related fields who are responsible for decision-making to reduce negative impact on environment.

2 Analysis of previous publications

Most publications on sustainable development have the following scholars: M. Zghurovs'kyj, P. Priyadarshini, H. Fredrickson, L. Zhao, S. González-García, J. Baleta, M.-H. Yuan, S.-L. Lo, A. Dawodu, A. Cheshmehzangi. Was made systematization of scientific publications in the following areas directly related to this research based on analysis of the works of foreign and domestic scientists:

- approaches to sustainable development [4, 6, 8, 10-13];
- development of indicators, indices to measure sustainable development [2, 14-21];
- construction of mathematical, software and hardware tools to assess impact of potentially dangerous enterprises on environment, taking into account economic indicators [22-33];
- training of specialists in the field of environmental safety and related industries [34-46].

However, further research should be dedicated to the questions of comprehensive and predictive assessments of environmental situation in technogenic territories in the context of sustainable development and skills development for professionals working in the energetic, environmental and related fields.

Aim: is to describe features of software application for sustainable development tasks and to outline directions of professional development of specialists responsible for management decisions in the energy, environmental and related fields.

3 The research results

3.1 Energy industry: from environmental security to sustainable development

One of the environmental safety assessing criteria of particular ecosystem is quality of life and health of population. There is need for purposeful impact (management) of ecological system in order to improve its organization and to achieve some beneficial effect.

Sustainable development models to measure system efficiency consist of economic, environmental and social subsystem were proposed in the research [10]. The result of the study is illustrated in 30 major Chinese cities. It shows main factors that affect their economic, environmental and social performance.

There is a need in planning and in policies that will be able to promote sustainable growth in order to

conserve resources and guarantee social services and the well-being of citizens. Socio-economic analysis is essential for establishing a comprehensive diagnosis of the resilience of urban and rural systems in addition to environmental perspective. The work [11] presents methodology to assess sustainability based on 38 indicators that include three bases of sustainability: social, economic and environmental. This methodology was tested in many municipalities in north-western Spain. The research results showed that the most resilient municipalities are located in the north of the region. Size of municipalities is important to measure stability. The publication authors noted that developed methodology is reliable and can be applied to other municipalities and cities.

Joint efforts and a multidisciplinary approach are needed to address global warming. Circular economics together with resource efficiency is focus of researchers and politicians. Sustainable development is a multidisciplinary topic. Interaction of energy, water and environment plays central role. In circular economy paradigm there is growing need for system integration when by-product of one system can represent resource for another. The research [12] highlighted issues of sustainable development of energy, water and environment systems. It was emphasized that more efforts should be made to further integration of these systems. All listed above leads to increase in complexity of such problem. It can be only solved by collaboration of many scientists from different fields of research.

Integration of energy, water and environment systems is important in the multidisciplinary concept of sustainable development as they represent basic necessities of humanity. Therefore, problems arising from the concept of sustainable development should be carefully addressed to conserve energy, water and environmental resources for future generations. Some recent developments in these major areas of sustainable development are discussed in [13].

3.2 Problem statement for sustainable monitoring for territories development

Environmental monitoring includes system of observations on factors that affect environment, process for assessing of the environment actual state, estimation, certain control and management capabilities. Environmental indicators are considered as separate indicators with significant impact on status of studied areas. Environmental indexes are considered as complex indicators.

Structural approach to assess the state of individual territories is developed for problems of impact analysis and technogenic impact. It is substantiated to determine indicators of environmental status (integral indices) based on data of urbanized territories monitoring in work [20]. Three types of environmental indicators are proposed to identify indicators of the urban areas environmental status:

- 1) the most informative among indicators recorded as result of measurements at the posts (concentrations of

the most dangerous substances);

2) multidimensional indices of ecological status of studied territories, based on set of measured indicators;

3) environmental risk estimation (probability distributions or risk fields) calculated on the basis of monitoring data.

Generalized estimations (indicators) of ecological status of these territories are determined on the basis of ecological monitoring data of the studied territories under conditions of high technogenic loads.

Site planning, construction and deployment of industrial facilities, land and natural resource management, vehicle management, agricultural development, accident or emergency simulation are typical sustainable development tasks that require the use of spatial analysis tools and technologies [2].

There are following tasks of monitoring, analyzing and evaluation of sustainable development of regions and individual territories: identification of spatial structure of systems under study (distribution of technogenic loads, distribution of risks and diseases, identification of dangerous zones); analysis of certain changes and determination of main trends for studied period (monitoring of dynamics of technogenic loads); predicting of possible scenarios for typical situations (in particular, assessing of potential impact of dangerous factors and effectiveness of management decisions).

One of priority tasks for assessment and modeling of sustainable development processes at territorial level is to determine stability limits of studied territorial systems under pressure of high technogenic loads.

Natural boundaries of sustainability in the concept of sustainable development determine state of biosphere and society which will preserve our civilization and basic natural resources for future generations. Therefore, it is necessary to determine such maximum permissible levels of load on separate territorial systems for which stable state can still be ensured [47].

Let's remember the definition of stability by Lyapunov in order to clarify the concept of the stability of dynamic systems. Trajectory of dynamic system can be considered stable if for any number of small deviations (that determine limits of stability of this system) such constraints can be specified for possible vibrations at which the system does not go beyond certain limits [48].

There are main stages of territorial systems research in order to determine stability limits to impact of technogenic loads.

1. Spatial analysis of man-made pollution monitoring data and identification of high-risk areas. In preliminary stages of analyzing monitoring data it is necessary to determine informative parameters (or environmental indexes) that are used to rank the sites and build environmental scales.

2. Results visualization of spatial analysis in the form of two-dimensional semantic scales, i.e. informative projections of semantic space of risks. It provides assessment and ranking of the studied territories by the indices of ecological status.

3. Visual analysis of technogenic loads dynamics over period of time in high-risk zones (maximum voltage

points) using stability scales and visual determination of the stability limits.

3.3 Analysis of tools and results

The authors of this publication developed an analytical and information system to monitor the technogenic environmental loads in order to study the spatial-distributed tasks of anthropogenic impact analysis on territorial systems. This monitoring system provides possibility to analyse complex processes and phenomena that reflect monitoring data of individual cities, regions or territorial systems. This software consists of several blocks, namely: block of statistical analysis and preliminary estimation of technogenic atmospheric loads; mathematical modeling and forecasting unit of atmospheric pollution and risks for the population; block of visualization and construction of ecological maps [26].

This system can be used as auxiliary tool for informational support of environmental monitoring tasks, monitoring of pollution from potentially dangerous objects, ecological safety management in conditions of technogenic pollution of atmosphere surface layer. It is necessary to support decision-making on ensuring civil protection of population and territories with increased technogenic loads. Developed software can provide local governments and other stakeholders with valuable information that is necessary to make the most effective decisions based on local outcomes.

Fig. 1 shows block diagram of software to manage environmental safety of urban areas. It includes tool to model and forecast technogenic environmental loads (in particular, atmospheric air) from stationary sources of pollution.

Methodological analysis of sustainable development processes requires determination of stability criteria of studied territorial systems. It needs to be known in order to calculate the restrictions on technogenic loads.

Task of defining such criteria can be seen as inverted to task of monitoring of technogenic loads at local level, i.e. task of those boundaries clarifying which can lead to catastrophic changes in systems under study.

Special attention should be paid to the development of tools for visual analysis of monitoring data and technologies for the construction of ecological scales among methodological tools aimed at determining the boundaries of urban areas sustainability. It provides visual reflection of changes dynamics in ecological status of territorial system over researched period.

Let's consider some of the graphical visualizations of processes under research based on computer-based visual observation of approaching boundary conditions process. It is necessary to take into account monitoring data and regulatory data on restrictions on maximum permissible concentrations and risks.

The proposed tool to change dynamics in ecological status analyzing and to determine the stability of urban areas boundaries to technogenic impact were tested on the example of the territorial system of Kyiv, Ukraine. The research was conducted using the city's atmospheric

air monitoring data from the Sreznevsky Central Geophysical Observatory from 2005 to 2018 [49].

In the previous stages of analysis, the most informative indicators of pollution were identified to monitor the dynamics of technogenic loads on the city. They have high danger class, large range of seasonal fluctuations and significantly exceed limits established by the current legislation. Dynamics peculiarities of technogenic influence on the surface layer of air were investigated on the examples of such dangerous substances – pollutants such as formaldehyde, nitrogen dioxide and carbon monoxide.

Values of risks for the population of different districts of Kyiv were determined based on the monitoring data. Chronic intoxication risk (RCI) and risk

of immediate toxic effects (RITE) were calculated using the formulas described in [50]. Dynamics of health risks can be monitored at specific points in the city according to these data. Estimates of risks for population for the study period are given in Table 1. Fig. 2 shows examples of risk maps due to air pollution in Kyiv, January-December 2017.

According to the given above data the highest values of technogenic loads and risks during the researched period were observed for Besarabska Square. It was marked as an area of high risk (observation point No 7). Also increased risk values in the observation period were noted at pollution observation stations (POS) of other central areas of the city (Nezalezhnosti Square, Peremohy Square, etc.).

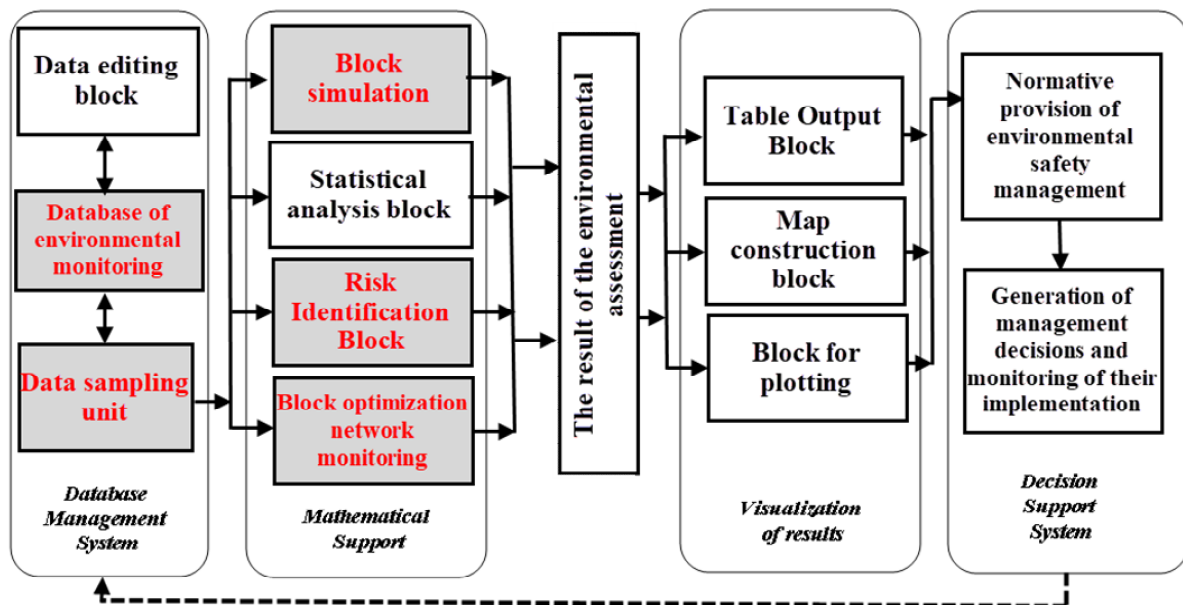

Fig. 1. Created software to provide safety.

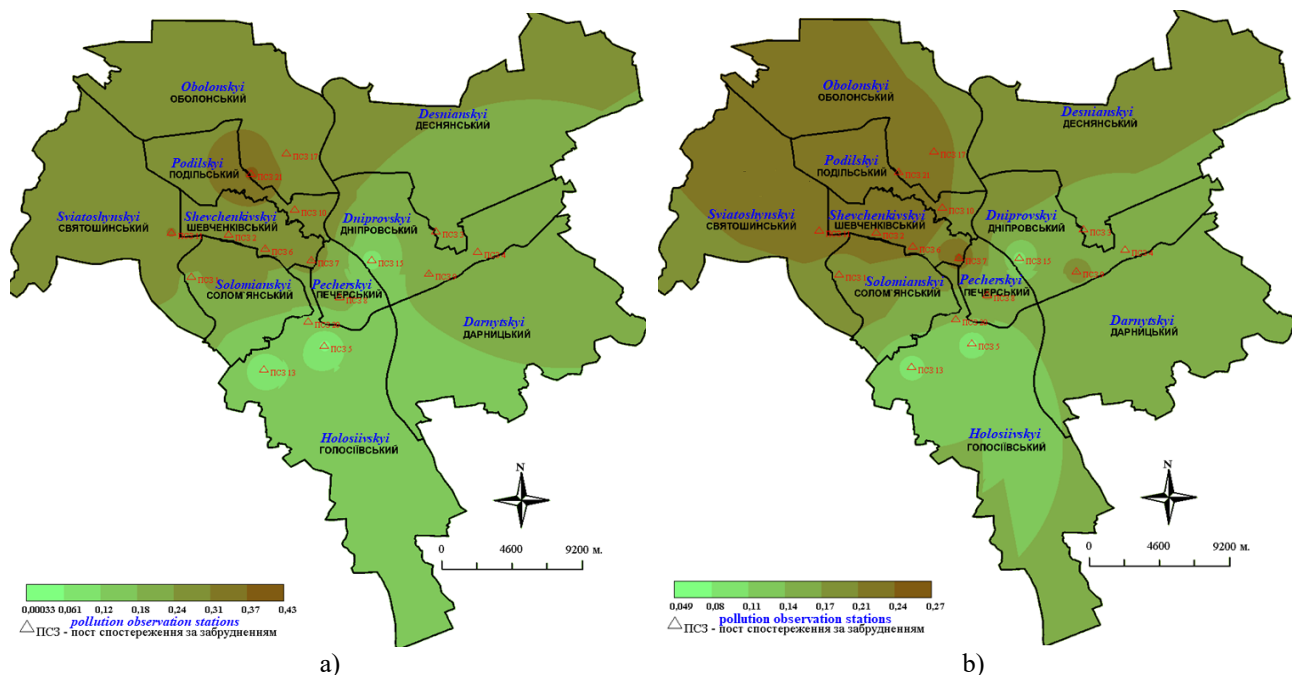

Fig. 2. RITE (a) and RCI (b) as a result of air pollution in Kyiv in January-December 2017 [26].

Table 1. Dynamics of risk values for the health of the population in Kyiv.

Location	2008		2011		2017	
	RITE	RCI	RITE	RCI	RITE	RCI
Peremohy Square	0.298	0.136	0.306	0.210	0.226	0.219
Demiivska Square	0.089	0.060	0.157	0.144	0.160	0.178
National complex "Ekspocentr Ukraina"	0.120	0.053	0.032	0.071	0.067	0.087
Darnytska Square	0.358	0.151	0.215	0.174	0.187	0.182
Maidan Nezalezhnosti	0.390	0.202	0.264	0.212	0.202	0.241
Bessarabska Square	0.472	0.275	0.321	0.255	0.211	0.296
Hydropark	0.140	0.063	0.025	0.068	0.026	0.077

Specialized visual tools of displaying monitoring data on exceeding the maximum permissible concentration levels and corresponding risk values were developed to monitor seasonal dynamics of technogenic loads on individual territories and to identify the most dangerous situations. It is possible to formulate certain sequence of graphic images and to determine the most dangerous deviations from the stable state comparing the results obtained by the authors.

On the first stage it is necessary to outline image of normal state located closer to the origin where exceeding the limit values does not reach critical values. Then it is necessary to distinguish maximum deviations from the norm directed in the opposite direction.

Fig. 3 shows dynamics of atmospheric pollution index for the period from 2015 to 2018 at POS No 7 (district of Besarabska Square). Obtained graph can be considered as the most meaningful reflection of

observations results. It takes into account data on main air pollutants in recent years.

Normal values are concentrated closer to coordinate axes five times lower than maximum values. The most dangerous situations form external contour. It starts from point above (6.2016) and is limited by maximum risks shown on the right part of chart.

Separate observations (monthly average pollution data) are indicated by rectangles showing month and year of observation. On the graph the monthly average values are interconnected in order in which the measurements took place.

It is possible to visually identify the most dangerous situations (or periods of maximum deviation from the norm) when local disturbances of stable condition are characterized by significant increase in population morbidity on the adjacent territories. It can be done by the proposed software for monitoring technogenic loads in certain territories.

Indices of ecological status of urban areas were calculated on the basis of monitoring data of Kyiv for analysis of sustainable development processes at local and regional levels, according to the recommendations given in [3]. At the present time the developed software modules were implemented at the Department of organization of civil protection measures of the SES of Ukraine, at separate unit of the Scientific and Technical Center of the state enterprise "NAEK Energoatom" (SE "NAEK Energoatom"). Recommendations on application of the developed software at territorial and interregional units of the State ecological inspection of Ukraine were obtained.

Fig. 3. Dynamic of the atmosphere pollution index at POS No 7 (2015 – 2018).

The developed software can provide population with information about the environment state, existing environmental risks/threats to safe living presented electronically. It is especially important when creating nationwide automated information and analytical system “Open Environment”.

There are estimations obtained from the analysis of real monitoring data and modeling of anthropogenic loads on particular areas. They should be correlated with those boundary conditions that meet the criteria of sustainability approved by international and national legislation to determine the boundaries of sustainability of urban areas.

3.4 Application areas of the software tools for advanced training of specialists in the energy sector, environmental and related fields

Application proposals of higher education institutions of Ukraine (National University of Bioresources and Environmental Management of Ukraine, Odessa State Ecological University, State Ecological Academy of Postgraduate Education and Management, etc.) for 2019 were analyzed. Analysis determined that these institutions offer training under the programs of additional professional education - and long-term skills development courses in full-time and part-time forms. The advanced training programs were developed in the field of Earth sciences (meteorology, agrometeorology, hydrology), ecology and others. Courses of advanced training in different directions and topics are offered: assessment of the state and technogenic impact of the motor transport complex on the environment, protection of the atmospheric air, design and operation of modern environmental monitoring systems, training of public environmental inspectors, basics of geoinformation systems and technologies course for users) and others. The offered skills development courses are aimed to improve professional activity of specialists to work in positions of managers and leading executives in management, ecology and nature management. Scientific enterprise “Infotech” developed an innovative virtual environment (consisting of a full-function web-based simulator and a distance training course) for training and skills development of staff of integrated energy system of Ukraine during the distance forms of training in order to improve the qualification of the personnel in the energy sector of Ukraine.

We believe that it is important to implement software tools to support managerial decision-making in the professional development of specialists in the energy, environmental and related fields. It corresponds to the modern world requirements for the training of specialists of new technological era. It will contribute to realization of the sustainable development concept of society. Experts using such software will be able to: identify previously unknown relationships between environmental parameters and environmental factors; identify and predict latent trends and patterns of development of environmental processes (identify hidden factors of influence, including threat factors;

systematize and integrate environmental data; develop optimization recommendations in energy, environmental and related industries; prepare preliminary reports and draft feasible decisions, etc.).

In 2019 the authors developed algorithms, mathematical and software tools to test environmental effectiveness of management decision-making. It is an important component in assessing of sustainable development of environmental systems. Also, the authors of this article provide advisory assistance and scientific support to organizations and institutions in order to improve skills of professionals in the energy, environmental and related fields (in particular in application of management decision support software).

4 Conclusions

The software was developed to solve problems of visual analysis of ecological status dynamics of territorial systems and to determine boundaries of sustainability of individual territories. New forms of presentation of monitoring data of anthropogenic loads and risks are presented to analyze the dynamics of anthropogenic impact and to determine the boundaries of stability of local systems. It reflects ecological situation dynamics in the space of informative features.

It is also important to improve skills of professionals particularly in ministries, business and organizational staff responsible for decision-making to reduce negative impact on environment and to train future professionals in this area. Only a few higher education institutions offer training courses for stuff who are working in the sphere of management, ecology and nature use. But it is not paid much attention on training to use managerial decision support software. The main areas of professional development of the specialists responsible for management are: conducting training seminars at the ministries, institutions and departments interested in implementing the developed systems; scientific and methodological support and advisory assistance in the process of implementation of the developed software; development and improvement of educational and methodological support for postgraduate students and trainees of advanced training of specialists responsible for management decisions in energy, environmental and related fields.

Use of geoinformation systems in environmental monitoring

Olena Pomortseva, Sergiy Kobzan, Andrey Yevdokimov, and Maksym Kukhar*

National University of Urban Economy in Kharkiv, 17, Marshal Bazhanov Street, Kharkiv, 61002, Ukraine.

Abstract. The purpose of the study, the materials of which are outlined in this article, is to uncover current trends in the development of environmental monitoring and the tracking of anthropogenic environmental impacts. To achieve this goal, it is proposed to use geoinformation systems to perform environmental monitoring and control, using appropriate software. For this purpose ArcGis software was used which allows monitoring the state of the atmosphere, its pollution and other deviations from the norm. The research was conducted exemplified by nine districts of Kharkiv. As a result of computer geospatial analysis, models and maps of urban pollution have been developed. In general, the intellectual analysis of geostatic models of emission distribution in the city allowed identifying and classifying zones of high concentrations of pollution and comparing them with air quality data. Methods of geostatistics transformed the data from a discrete to a continuous form of representation. Further studies in this area may be related to the improvement of geostatistical data analysis and pollution distribution prediction methods. As an example, mathematical formulas were presented to determine the atmospheric pollution index and the true or predicted pollution index, which can be determined on the basis of the data obtained and represented by elements of the ArcGis software package in a discrete and continuous form.

1 Problem statement

The natural environment of Ukraine is contaminated with a large number of various toxic chemical elements and compounds. Under these conditions, the task of ensuring the environmental safety of the population is urgent.

In the implementation of environmental monitoring and environmental control, a common functional element is to conduct observations and evaluate the data obtained by some characteristics. In environmental control, the objects of observation are anthropogenic objects or economic activity as a whole. In the course of environmental control, the managerial influence on the observed object is exercised, in the case of environmental monitoring – obtaining objective environmental data, predicting possible changes in time and space under the influence of natural and anthropogenic factors. The task of observation is to monitor the state of the environment, detect and predict negative changes, and provide timely information in the established manner [1]. In this case, the detection of any deviations in the state of atmospheric air, surface water and soil is a signal for taking control actions to prevent environmental pollution.

Modern technologies allow us to identify environmental problems at the stage of their occurrence, thereby facilitating anthropogenic load on the environment. Significant experience has been accumulated in the world practice in the field of monitoring the harmful effects of human activity on the

environment. [2]. At present, objective opportunities and needs for the implementation of various technical and technological measures – special information technologies in the field of ecology – have appeared in Ukraine [3].

The two main methods for tracking the impact on the environment and what is happening in it are monitoring and control. The main difference between them is the dynamism of the first and the static character of the second. The most interesting for analysis is monitoring, which, unlike control, provides more research opportunities and is not so cruel for its purposes. Static control and dynamic monitoring are only external characteristics. In fact, in both cases we are talking about special information technologies [3, 4].

Thus, the topicality of scientific developments in this field becomes clear. The purpose of this article is to reveal the current trends in the development of environmental monitoring and the monitoring of anthropogenic impact on the environment.

2 Analysis of recent research and publications

Modern technologies allow us to explore the environment and make decisions about actions to eliminate the negative consequences of human activity, or support and improve life.

This issue is being addressed both internationally and regionally.

Research [5] examines the effective use of state-of-the-art technologies for monitoring air conditions using both specialized equipment and portable devices based on the Android operating system. This paper discusses the implementation of an air quality analysis system based on geoinformation systems.

The study [6, 7] proposes the use of specially designed mathematical software for the implementation of environmental monitoring, the task of which is to solve specific problems, taking into account the situation in a particular locality. And as a basis for the implementation of this mathematical apparatus is used geographical information systems.

Ukraine is one of the industrial-agricultural countries. Until recently, the share of heavy industry has been 60% of the country's gross domestic product, which is substantially higher than in Western European countries where the figure is about 35%. It is heavy industry enterprises that form the main man-made burden on the environment. A significant part of industrial enterprises (more than 80%) is located in cities and urban-type settlements. About 70% of the country's population lives here. There are 436 cities and 925 urban settlements in Ukraine. According to statistics, up to 90% of gaseous, liquid and solid wastes are generated in urban areas and about 10% in rural areas. Many cities of Ukraine are characterized by a difficult ecological situation, due to the presence and concentration of enterprises of ferrous and non-ferrous metallurgy, heat power industry, chemistry and petrochemistry, mining and cement plants. Such cities are the leaders in terms of air pollution.

In large cities with large traffic flows, the content of carcinogenic substances of benzopyrene type in the air is 2-3 times, and in the centers of ferrous metallurgy about 12 times higher than in small cities or rural areas. Soil pollution in cities is mainly related to emissions from motor vehicles and industrial enterprises. Pollutants are accumulated or washed out by atmospheric precipitation from the air basin within a radius of 5 km from a stationary source of emissions.

The establishment of environmental management and regulation of environmental processes requires serious technical support and the use of modern technologies to solve problems related to environmental protection. For effective analysis and visualization of spatial information, there exist powerful tools – geographical information systems which not only allow you to create electronic maps based on databases, but also solve problems of any complexity due to the diverse analysis of available spatial information [6, 7].

Modern production, economic and other human activities are associated with the use of a huge amount of various substances, chemical compounds and other materials. This causes a significant burden on the environment, associated with a reduction in living space for untouched wildlife, penetration into the biosphere of substances unusual for their natural circulation, and a violation of the energy balance. The power of this load has reached such a level that it is quite capable of causing serious environmental crises and disasters [8].

Ukraine has significant land resources. As a result of irrational agricultural use, soils lose humus, they are

polluted by chemicals, undergo water and wind erosion, are flooded, become salty, and plough land is reduced [9, 10].

The methodology and methodology of using geoinformation technologies in the performance of environmental monitoring is presented in scientific works [8-13].

3 Outline of the basic material

Currently, in the territory of Kharkiv and the region there are a number of environmental problems that cannot be resolved over the years and have an extremely negative impact on the environment. Kharkiv region ranks fifth in terms of industrial production and fifteenth in terms of generation and disposal of industrial toxic waste. The main contribution to air pollution is not made by enterprises (stationary sources of pollution), but by an ever-growing fleet of cars (mobile sources). And this significantly changes the whole map of air pollution in the city.

As a result of the analysis of pollution sources, the following were identified:

- Motor transport.
- Large enterprises – KhTP (KhTZ), CHPP-3 (TETs-3), CHPP-5 (TETs-5), Coke Plant (Koksokhimzavod).

It should be noted that the main pollutants that exceed the maximum allowable concentrations are dust, phenol, formaldehyde, carbon monoxide and soot. Other important factors of the unsatisfactory ecological state in the city are also a decrease in the number of green spaces, lack of sanitary zones of enterprises, natural features, poor management and poor environmental control.

An extremely important problem in the second most populous city of Ukraine is the problem of waste disposal:

- Lack of disposal of most components.
- Low control.
- Absence of private sector garbage collection system.

A vast scale of capital and housing construction, an increase in the population of Kharkiv, due to the dynamics of its development as an industrial and cultural center, led to a significant expansion of the city's borders. Currently, the city covers an area of 303 km². Despite its large size, the city is characterized by compactness. A distinguishing characteristic of the city is that it is one of the greenest among the cities of that kind. Green areas of parks and gardens, boulevards and squares make up 12 628 ha. There are more than 17 m² of green space for one resident of the city.

The use of geographical information technologies makes it possible to visualize the available data on the contamination of the territory by this or that substance, to perform statistical analysis of the data, to study the distribution of data, to perform their transformation, to compare the existing state of pollution with the maximum allowable concentration.

Modern geoinformation systems, from developers such as: Spatial Manager, ActiveMap GS, GisMapServer, IndorCAD / River, MapInfo MapX, do

not contain tools for monitoring indicators of air pollution by harmful substances, so there is a need to create software applications based on existing geographical information systems using modern methods of geostatistical analysis. A system for monitoring air pollution should allow modeling and analysis of polluted air flows.

In connection with the above, the importance of scientific, methodological and computer support for monitoring tasks, a comprehensive assessment of atmospheric pollution and determining the level of environmental risk for individual territories where modern geographical information technologies and geoinformation systems that provide spatial mapping of territorial objects in the form of electronic environmental maps, plays a decisive role.

The functional diagram of the developed geoinformation monitoring system consists of a data collection subsystem, a data storage subsystem based on geodatabase management systems, a data integration subsystem that allows you to analyze and visualize data using geoinformation and geostatistical methods; subsystems for publishing analysis results in the form of cartographic, tabular materials and reports.

Based on the statement of the problem, a local geographical information systems was developed, designed to assess the technogenic load of the air environment of the city of Kharkiv. Figure 1 shows the structure of this geographical information systems with respect to the direction of movement of accumulated data in the system.

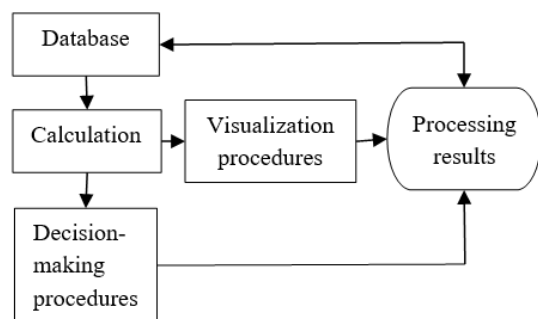

Fig. 1. The scheme of the developed geographic information system.

Using the database allows you to manage your data – to edit and add new records. The system database collects atmospheric air pollution monitoring data for a specific area and is able to add new data and update old records if necessary. Also, the physical properties of pollution sources; maximum permissible harmful substances emissions; digitized terrain maps and substrate maps; data processing results using system procedures should be stored in the database of this monitoring geographical information systems.

Data is one of the most important components of geoinformation systems. Spatial data and related data can be updated with the required amount of time. In the process of spatial data management, geographical information systems integrates spatial data with other

types of data, and uses the database to organize and store existing data.

According to the existing data collection system, statistical information describes in the most detailed and complete manner the volumes and locations of major sources of atmospheric emissions. To calculate air pollution in Kharkiv, we used statistical data on environmental emissions for the period 2015 – 2019.

To display the objects of the city's industry, a personal geodatabase with the necessary layers was created [11]. The master plan of the city of Kharkiv, as amended in 2014, served as baseline data. As a result, a digital model of the territory of Kharkiv was made taking into account the number of enterprises – a darker color (Fig. 2).

Fig. 2. Digital geoinformation model of the territory of Kharkiv.

The digital model shows that the main concentration of industrial enterprises (namely their share is the highest in pollution) is in Nemishlianskiy, Kholodnohirskiy and Novobavarskiy districts of the city.

The attribute table of the “Contamination” layer was filled with data over the last five years (Fig. 3).

Having analyzed the amount of emissions of harmful substances into the atmosphere during this period, it was concluded that the amount of harmful substances as a whole is decreasing. The reason for the decrease in the amount of harmful substances in the atmosphere is due to the decrease in capacity in most large industrial enterprises. This conclusion illustrates the comparison of formaldehyde levels in the city air in 2019 (figure on the right) with 2015 (figure on the left) (Fig. 4).

The reasons for the continuing pollution of the atmosphere include the fact that not all operating enterprises which are sources of harmful emissions have built emission treatment facilities. One of the existing cleaning methods is the installation of cyclones (dry cleaning method). But it should be noted that this method of cleaning allows reducing harmful emissions

to the permissible maximum allowable concentrations not in all cases. Only a few companies carry out regular production controls on the emissions and efficiency of treatment plants.

Also, the reason for the unsatisfactory state of the atmosphere is due to the fact that enterprises and organizations have got obsolete equipment that requires being repaired or replaced with a new one. One of the possible ways to reduce the technogenic load on the atmospheric air is closing outdated boiler houses and connecting heat consumers to boiler rooms equipped with modern treatment plants.

The created geographical information model made it possible to obtain histograms, clearly showing the

pollutant emissions not only by types of harmful substances (Fig. 5), but also by industries which are the sources of these emissions. The figure shows the city's emission levels in 2018. It was also established that during this time interval the main enterprises that polluted the atmosphere were the "State Specialized Enterprise "Kharkiv State Interregional Special Combine" and the PJSC "Frunze Plant".

In 2015, the emissions of harmful substances were much higher (Fig. 6). The main enterprises from which these emissions were caused were State Enterprise "Malyshev Plant" ("Zavod im. Malysheva") and JSC "Turboatom".

Fig. 5. Emissions of pollutants (thousand tons) into atmospheric air by types of harmful substances.

Fig. 6. Comparison of average emissions of pollutants in Kharkiv in 2015 and 2019

Assessment of the technogenic load on the environment, namely on the air environment, may be appropriate when using local geographical information systems map-based monitoring. Unpretentiousness to hardware costs, low cost of development and implementation, flexibility in designing, making amendments and improvements, the ability to build high-precision graphical models within local territories provides this type of geographical information systems advantages compared to a number of global systems existing and presented on the information market. Further development of this geographical information systems should be aimed at assessing, classifying the level of pollution, modeling the form and effects of pollution. For this, two indicators can be used – the air pollution index (*API*) and the pollution index (*PI*).

The air pollution index is used for the integral assessment of the condition of the air. This is a complex air pollution index which is calculated by the sum of several major pollutants when translating the absolute values of each into the maximum allowable concentration (*MAC*). The conversion of absolute values into the air pollution index (*API*) makes it possible to more effectively take into account the environmental damage caused by pollutants of various degrees of harmfulness.

According to state sanitary rules [14], all of the listed indicators have a specific algorithm and formulas for calculation. These formulas are presented below

$$API = \sum_{i=1}^n \left(\frac{q_i}{MAC_{iMS}} \right)^{a_i} \quad (1)$$

where n – number of impurities taken into account in the calculation;

q_i – concentration of the i -th substance, mg/m^3 ;
 MAC_{iMS} is the maximum single *MAC* of the i -th substance, mg/m^3 ;

a_i – the ratio of the hazard ratio of the i -th substance with the harmfulness of substance III hazard class (a_i of I class is 1.7, a_i of II class – 1.3, a_i of III class – 1.0, a_i of IV class – 0.9).

The assessment of the actual or predicted (estimated) level of air pollution is performed by comparing the index of pollution with one substance or the total pollution index (ΣPI) with a mixture of substances with the maximum allowable pollution index (*MAP*). A level

not exceeding the *MAP* shall be considered admissible.

Indicator of maximum permissible atmospheric air pollution is a relative integral criterion for estimation of atmospheric air pollution of inhabited places, which characterizes the intensity and nature of the joint action of the whole set of polluting substances (*PS*) present in it. *MAP* is calculated for each case on the basis of experimentally determined and approved in the established order coefficients of combined action (C_{Ca}), which reflect the nature of the combined biological action of polluting substances (*PS*) simultaneously present in the atmospheric air. *MAP* is calculated by the formula:

$$MAP = C_{Ca} \cdot 100\% \quad (2)$$

Indicator of actual or predicted air pollution by one substance is calculated by the following formula:

$$PI = \sum_{i=1}^n \left(\frac{C}{MAC} \right) \cdot 100\% \quad (3)$$

where C – actual or predicted concentration of a specific substance, mg/m^3 ;

MAC – maximum allowable concentration of this substance, mg/m^3 .

Assessment of air pollution is carried out taking into account the rate of exceeding the *PI* of their normative value (*MAC*) and includes the determination of the level of pollution (permissible, unacceptable) and its degree of danger (safe, slightly dangerous, moderately dangerous, dangerous, very dangerous) [15].

Solving these problems, as well as supplementing the compute core of the system with decision-making and forecasting procedures, are the main areas of further development of the developed geographical information systems.

ArcGis software was used to determine the environmental situation of the city and build the electronic map. The environmental map reflected the spatial features of changes in the state of pollutant emission. The map made it possible to compare the state of environmental pollution by years. An ecological map was also created that provided the opportunity to link the geospatial distribution of industrial enterprises with certain types of pollutants. In contrast, for other pollutants, industrial areas are not a major factor. These findings allow regional managers to develop appropriate stabilization measures.

4 Results

1. A digital geographical information model of the Kharkiv city was developed, with a significant amount of attribute data input.
2. Calculations of maximum permissible indicators of pollutants in the atmosphere.
3. Models of comparison of formaldehyde in city air in 2015 with 2019 have been developed.
4. Models of comparison of pollutant emissions into the atmosphere based on monitoring results are developed.

5 Conclusions

In the study, using the ArcGis software package, ecological models were developed and a map of the level of pollution with harmful substances in the city of Kharkiv was compiled. This map will provide an opportunity to set the necessary operating modes of polluting enterprises so that they do not harm the environment and the population. It will also allow regional leaders to make reasonable and correct decisions regarding environmental activities. The very principle of constructing ecological maps and database structure will be effective at any objects, so the developed geographical information systems can be distributed to any administrative units and industrial enterprises.

In general, an intelligent analysis of the geostatic models of the emissions distribution in a certain territory made it possible to identify and classify zones of high concentrations of pollution and compare them with data on air quality. To process statistical data in a single locality, geostatistical methods were used to transform data from a discrete to a continual representation. Further research in this direction may be related to the improvement of the geostatistical analysis of data and methods for predicting the distribution of pollution. As an example, mathematical formulas were presented to determine the atmospheric pollution index and the actual or predicted pollution index. These indicators can be determined on the basis of the data obtained in the study and presented using elements of the ArcGis software package in a discrete and continual form.

Abstract. A methodology has been developed for calculating the number of migratory birds in the territory of wind power farms and the StatBirds1 program for statistical analysis of bird monitoring results at the wind power farm “Prymorsk-1” on the coast of the Sea of Azov in the Zaporizhzhya Region. In the process of accounting, the type and number of birds, the direction and type of flight (transit, feeding, demonstration), the height and length of the flight, the time each bird was in the observation areas were recorded. Monitoring was carried out during 24 days in 2017 at three observation areas in the territory of the wind farm.

1 Introduction

The capacity of Ukrainian wind power farms (WPF) has tenfold increased in the last 9 years [1]. Ukraine’s energy strategy envisages the construction of new WPF, which will be able to produce at least 30% of all electricity from renewable energy sources by 2030 [2]. Taking into account all characteristics of the Pryazovskyi district, it should be stressed that this district has a number of advantages for the wind power farms construction in comparison with other regions of Ukraine. With a small area of the nature reserve fund, there is a small number of objects with environmental status, which predetermined the choice of a location for the placement of several high-capacity wind power farms (Botievo wind power farm, Prymorsk-1, Orlovsk wind power farm, Prymorsk-2).

Botievo wind power farm (capacity 100 mW) is the first largest wind power farm in Ukraine. The “Prymorsk-1” WPF with a capacity of 100 mW produces annually about 700 million kilowatt-hours of clean electricity [2]. This wind power farm is located on the shores of the Azov Sea, where several wind power farms with similar technical parameters are functioning and being built within the 60 km distance.

Current projects and developments in the field of renewable energy create new threats for birds [3]. At the UNO Climate Conference in Bonn, several researchers said that wind turbines are becoming a particular problem for migratory birds. The negative impact of wind power farms on ornithological complexes is greatly exaggerated, since wind power farms are point objects. Their danger to birds does not outweigh the danger of transmission lines, which, in comparison with wind power farms, occupy vast

areas. The main threat to birds is caused by the possibility of their collision with the turbines in the case if the wind turbine units are located in places of their intensive movement. In the work [4] it is reported that the death rates of birds at the first small wind power farms are estimated at 2.1–63.8 individuals / a turbine / a year. The technical characteristics of the new generation of rotors provide a threefold negative impact reduction on the birds [5]. A large number of studies have been devoted to the study of the influence of wind power on ornithological complexes [3; 6; 7; 8].

Wind power farms at the Azov Sea seaside are located in one of the most powerful migration routes in Eastern Europe - the Azov-Black Sea route, which predetermined the need to study the state of biodiversity in the territories of wind power farms [9; 10]. Project work to substantiate the impact of wind power farms on bird ornithological complexes within Prymorsk district of Zaporizhzhia region was carried out in 2011-2017 in accordance with the recommendations of the Scottish Natural Heritage Foundation [11]. On the basis of the obtained data, an analysis of the possibility of birds’ death in the case of their collision with the rotor blades at the wind power farm Prymorsk-1 was carried out [9].

To estimate the possible number of collisions, information on the total number of collisions on a wind power farm is necessary. As a rule, it is necessary to process a considerable amount of information in order to monitor all this data, the analysis of which is not possible without the application of modern information and communication technologies. The purpose of this work is to develop and test the calculation method of the number of birds in the wind power farms territory. To achieve this goal, the following tasks had to be solved:

* Corresponding author: evs1938@gmail.com

- to conduct the research on ornithological complexes at the observation sites using the recommendations of the Scottish Natural Heritage Foundation,
- to develop ICTs that provide statistical analysis of monitoring results,
- to create the mathematical model for determining the number of birds based on the observation results of bird migration,
- to test the calculation method on the example of monitoring results on the Prymorsk-1 wind power farm territory.

2 Methods of gathering information and statistical processing of observation results

2.1 Physical characteristics of the territory of the Azov Wind power farms

The wind power farms border with the sea of Azov on the south, and are surrounded by agricultural fields from the other sides. There is no natural tree vegetation on the WPF areas, buffer zones and adjacent territories. Tree species are found only in the form of artificially grown plants and along roads. The monitoring of bird migration on the territory of Prymorsk-1, the area of which is 10.1 km², was carried out at three points of PS1, PS2, PS3 (Fig. 1), which by their natural parameters are close to the characteristics of the wind power farms and to the areas of all the power farms. The observation site areas of PS1, PS2, PS3 were, respectively, 0.50 km², 0.86 km² and 1.23 km². The total area of observation sites was 2.59 km². The location of the PS provided a distance of no more than 2 km between the wind park and the observation point. The observation sector did not exceed 180° for each PS.

Fig. 1. Scheme of observation points location within the Prymorsk-1 wind park.

2.2 Methods of observation

Methodological developments in the study of ornithological situation in the territory of Prymorsk-1 were based on the recommendations of the Scottish Natural Heritage Foundation [11]. Measurements were made within 24 days in 2017. The duration of

observations in different seasons is shown in Table 1.

Table 1. Duration of bird observation in different seasons in 2017.

Observation cycle	Duration of observation T , hours			
	PS1	PS2	PS3	$\sum T_i$
Spring migration	24	24	24	72
Nesting	42	42	42	126
Autumn migration	36	36	36	108
Winter period	42	42	42	126
Total	144	144	144	432

The flight altitude of each bird was recorded at the time of its appearance at the observation area. Subsequently, measurements and bird classification (into several groups) were carried out every 15 seconds. Considering the way of bird interaction with rotors it is possible to distinguish three groups:

- a group of birds with a flight altitude of up to the lower edge of the rotor (48 m),
- a group of birds with a flight altitude above the upper edge of the rotor (182 m),
- a group of birds at risk (RZ) of a collision with rotors at flight altitude between the lower and upper edges of the turbine.

Spring migration was studied in the first and third decades of March, as well as in the first decade of April. The nesting period was studied on April 25-28.04 and May 25-28.05. Autumn migration was studied in the second decade of September, the first and second decades of October and the first decade of November. Winter observation was combined with a wintering period in the second decade of January and a breakup period of wintering in the second decade of February.

The observations were carried out from 8.00 to 11.00 in the morning and from 13.30 to 16.30 in the evening with the determination of the type of birds, their number, direction of flight, type of flight (transit, feeding, demonstration), altitude and length of flight, the total time of the bird presence at the observation site, time spent at various heights.

2.3 The tool base

During the monitoring process, the following equipment was used: binoculars (20x); optical tubes *OPTOLYTH* 20-60x80; optical tube *VIXEN* 20-60x100; optical tube *VIXEN* 20-60x80; a laser device for altitude determining *NICON Forestry* 550; devices for the coordinates determining *GARMIN GPS MAP* 78s.

2.4 Software

The primary processing of the observation results was carried out using the “*WebBirds*” application created by O. Annenkov [10]. The database management system (DBMS) “*WebBirds*” is a convenient tool for storing, accumulating, adjusting and processing the results of bird monitoring at the power farm. The DBMS is based on the tables of the recorded bird species, the number of individuals at various observation points, the territory of

the wind power farm and other parameters of the study. The Web application allows you to create new records from mobile devices, add and update existing data on the number and types of birds, places of their seasonal placement, flight altitude, type and direction of migrations, as well as generate accounting results according to the specified parameters in a convenient form.

To conduct a statistical analysis of the observation results in this work, we created the *StatBirds* program in the *Microsoft Visual Studio Community 2017* software development environment based on *Windows Forms* technology. The program presents the specific parameters that characterize the birds behavior on the territory of the Prymorsk-1 wind power farm: bird species, observation date and time, number (amount) of birds n , number of the observation area PS, flight direction of migrant birds, method (type) of presence at the observation site (transit, stern, demonstrative), the altitude and length of the trajectory in m on this area, the time spent by birds in the observation areas (t_1 – the total time, t_2 – at the height up to the lower level of the wind wheel edge, t_3 – at the height between the lower and upper level of the wind wheel, t_4 – at the height over the upper level of the wind wheel edge), the coefficients k_1, k_2, k_3, k_4 , which determine the birds activity at different heights. The values k_1, k_2, k_3, k_4 were calculated by the formula $k_i = t_i n_i$ ($i = 1, 2, 3, 4$).

2.5 Methodology of the migrant number calculation

Let the registration of birds of the j -th species be carried out at the observation site of PS with area S_0 during the time T . Denote the density of birds that are in the air per unit of time, as $n_j(t)$. The total number of birds in flight conditions N_j , per square unit, is equal to

$$N_j = \left[\int_0^T n_j(t) dt \right] / (S_0 T).$$

T can be divided into smaller intervals $\tau_i = \tau_1, \tau_2, \tau_3 \dots$ with a bird density of n_{ij} . We require that the set of intervals $\{\tau_i\}$ contain all the elements of the set $\{t_i\}$ that correspond to the time values t_i of birds in the number n_{ij} at this observation point. In this case, the value of the integral is estimated by

$$N_j = \left[\int_0^T n_j(t) dt \right] / (S_0 T) \approx \left(\sum_i n_{ij} \tau_i \right) / (S_0 T). \quad (1)$$

The parameter $K_j = \sum n_{ij} t_{ij}$ in formula (1) characterizes the activity of birds presence at the PS area. If the parameters that determine the migration through the PS area and the adjacent region of square S are the same, then the number of birds of the j -th species in flight condition in region S is determined by the expression

$$N_{jS} = SK_j / (S_0 T) = S \sum n_{ij} t_{ij} / (S_0 T). \quad (2)$$

The activity coefficient K_j and formulas (1), (2) do not take into account birds on the ground, therefore, the total number of birds in flight condition and on the ground per square unit is

$$N_j = \beta_j K_j / (S_0 T) = \beta_j \sum n_{ij} t_{ij} / (S_0 T), \quad (3)$$

where the coefficient $\beta_j \geq 1$ depends on the type of bird, time of day, season and other indicators.

In this case, the total number of birds in region S in flight condition and on the ground is

$$N_{jS} = \beta_j SK_j / (S_0 T) = \beta_j S \sum n_{ij} t_{ij} / (S_0 T), \quad (4)$$

The value of β_j varies over a wide range. It can be expected that for individuals that fly long distances in the spring and autumn seasons, the value of β_j is about 1-5. In the case of local birds that live in this area or constantly move from the habitat to the place of feeding, the value of β_j is most likely in the range of 10-100.

The total density of birds of all species N per square unit in accordance with formula (4) is

$$N = \sum_j \beta_j K_j / (S_0 T) = \sum_j \left(\beta_j \sum_i n_{ij} t_{ij} \right) / (S_0 T). \quad (5)$$

Knowing the density (5), we can estimate the total number of individuals of all species N_s on the territory S adjacent to the wind park, according to the formula

$$N_s = S \sum_j \beta_j K_j / (S_0 T) = S \sum_j \left(\beta_j \sum_i n_{ij} t_{ij} \right) / (S_0 T). \quad (6)$$

3 Bird monitoring results at observation points and statistical data processing

3.1 Measurement results

In 2017, 5923 birds of 45 species were recorded, 2061 of which were recorded at PS1, 1824 at PS2 and 2038 at PS3. Most of them were in the spring (50%) and autumn (35%) periods. The primary processing of the results was carried out using the WEB application “*WebBirds*” [10]. An example of registration of birds in paragraph PS3, which were recorded during one day on 03/13/2017, is presented in part of the table 2, where the following designations are used: species of birds (*Species of birds*), time of day (M – morning from 8.00 to 11.00, Ev – evening from 13.30 to 16.30), number of birds of the observed species (n), direction of flight Dir (N – North, S – South, E – East, W – West), type flight – *Type* (Tr – transit, F – feeding, Dem – demo), height (H) and flight length (L), total time spent by individuals t_1 in point of registration, the time spent by individuals at a height less than the level of the lower edge of the rotor $H_1 = 48$ m (t_2), the time spent by individuals t_4 at a height greater than the level of the upper edge of the rotor $H_2 = 182$ m, the time spent by individuals in RZ t_3 at the height between H_1 and H_2 , the total activity coefficients of birds presence at the observation point $K_1 = t_1 n$ and in RZ $K_3 = t_3 n$.

According to the table 2, on the PS3 area, within one day, March 13, 2017, 101 individuals of 9 species were recorded. 71 birds were observed in the morning time, and 30 – in the evening. The greatest activity is related to the species *Sturnus vulgaris* (37 individuals). Most of the birds were found at heights lower than the lower boundary of the RZ, i.e. below 48 m. One *Circus aeruginosus* bird

was observed in the RZ at the height of 60 m for 34s. Birds did not fly above the upper boundary of the RZ on this day. The activity coefficient of birds K_1 for all heights on the PS3 site within one day 03.13.2017 is 2570 s., that is two orders of higher than the coefficient value $K_3 = 34s$, that is related to the RZ. Similar results were obtained at all areas.

Table 2. Monitoring results at PS3 area within one day 03.13.2017

The vast majority of birds in winter period (86.9%) were recorded at heights of up to 10 m. 13.1% of individuals were in the range of 10-50 m. No birds were found in the risk zone of 51-150m. The main migration vectors were the east (31.21%) and the southeast (23.76%). The number of migrants in the southern (11.83%) and north-eastern (11.73%) directions was two times lower. For each of the other areas, about 6% were taken into account, Fig. 2.

Fig. 2. Directions of bird movements in winter period (quantity in %).

In the spring migration period, 98.4% of birds were recorded at the safe heights of up to 50 m. 1.6% of all recorded birds were found in the risk zone. About half of the birds (67.9%) flew to the northwest, north, northeast and east. Additional flight directions were the southwest (12.1%) and the southeast (9.4%), Fig. 3.

Fig. 3. Directions of spring migration of birds (quantity in %).

Altitudinal movements of birds in the nesting period were distributed as follows. All birds at heights of less than 50m were recorded. The vast majority of birds were observed in the surface altitude range up to 10m (92.4%). This nature of the altitudinal distribution is explained by

the fact that most birds at this time of year are in their nests. The main directions were the north, the northeast, the east (only 55.1%) and the southeast (22.0%), Fig. 4.

Fig. 4. Direction of bird flight in the nesting period (quantity in %).

Observations of autumn migration showed that 99.4% were at safe altitudes. In the risk zone, 6 birds were recorded (0.6%). The main directions of migration were the northeast, the east and the southeast (68.8%), Fig. 5.

Fig. 5. Directions of autumn bird migration (quantity in %).

Statistical processing of bird monitoring results was carried out using the *StatBirds* program. The number of registered birds of various species in 2017 in the most dangerous altitude range (RZ) is given in table 3. The general coefficient of activity K_3 for them turned out to be equal to $K_3 = 2196$ s, which is two orders less than the value $K_1 = 170048$ s, which relates to the entire ornithocomplex.

It follows from the Table 3 that 72 birds were found in the RZ at altitudes between 48 m and 182 m. Most of them

belong to *Larus ridibundus* (43 birds) and *Merops apiaster* (15 birds). The number of individuals for *Buteo buteo* and *Circus aeruginosus* was 5 and 9, respectively.

Table 3. Bird monitoring results in RZ on all observation areas.

Bird species	Season	Area number(s): the number of birds n	t, s	K_3
<i>Buteo buteo</i>	Summer	1,2,3: 0	0	0
	Autumn	1: 1,1	36,7	43
	Autumn	2: 1,1	51,30	81
	Autumn	3: 1	18	18
	Winter	1,2,3: 0	0	0

	Autumn	1,2,3: 0	0	0
	Winter	1,2,3: 0	0	0
<i>Larus ridibundus</i>	Spring	1: 5,7,3,8	42,25; 19,26	650
	Spring	3: 7	42	294
	Summer	1,2,3: 0	0	0
	Autumn	3: 7,6	28,15	286
	Winter	1,2,3: 0	0	0

The average density of the total number of birds in flight condition N and on the ground per square unit is determined by the formula (5). The parameter β_j in this formula depends on the type of individual, time of day, season, terrain characteristics, etc. Let's suppose that the average value of β_j is 30.

In this case, the total number of birds in flight condition and on the ground on three areas PS1, PS2, PS3 will be 4.8. The characteristics of the observation points and the surrounding areas of the power farms are identical. The coastal area, where four wind power farms are located, is approximately 10^3 km². The total number of birds in this zone and at the Prymorsk-1 power farm according to formula (6) is 18.8 and 4800, respectively.

3.2 Distribution of birds in flight condition by monitoring areas

The density of birds at different areas of observation is determined by formula (5), where the coefficient β_j should be set equal to 1. The calculation results are presented in the table 4. When compiling the table 4 the following designations were accepted:

N is the estimated value of the number of birds in flight condition (in brackets is the average value of the number of recorded birds a , referred to one day of registration on the area of 1 km²),

N_m, N_{Ev}, a_M, a_{Ev} – the same separately for morning M and evening Ev observations,

$N_{Tr}, N_{St}, a_{Tr}, a_{St}$ – the same for birds with different types of flight (transit Tr and feeding St , respectively),

N_E , N_{SE} , a_E , a_{SE} – the same for birds per day, with the preferred direction of migration in the eastern E and the southeast SE directions, respectively.

From the table 4 it is obvious that the average number of birds a , recorded in various cases, is three orders of magnitude greater than the number of birds N that are only in-flight condition.

Table 4. The calculated total number of birds in flight condition N_F and the number of recorded birds a (in brackets) when measured per 1 km².

	PS1	PS2	PS3
$N(a)$	172 (0.366)	88 (0.149)	69 (0.083)
$N_M(a_M)$	85 (0.179)	45 (0.075)	38 (0.047)
$N_{Ev}(a_{Ev})$	87 (0.187)	44 (0.074)	31 (0.036)
$N_{St}(a_{St})$	63.5 (0.127)	34.2 (0.058)	48.5 (0.026)
$N_{Tr}(a_{Tr})$	108.5 (0.239)	54 (0.091)	47 (0.057)
$N_S(a_S)$	48 (0.084)	19.5 (0.030)	20.6 (0.026)
$N_{SE}(a_{SE})$	32 (0.067)	17.7 (0.032)	11.9 (0.012)

Morning and evening measurements do not differ greatly from each other. Most of the birds flew in transit, while the eastern and south-eastern directions of migration were the main ones. The activity of birds at different areas of observation was different. The highest activity was recorded at PS1. There is a linear correlation between the parameters N and a

$$N = A + Ba \quad (7)$$

The table 5 presents the correlation coefficients K_{Na} , between the values of N and a , calculated for each observation area and in general for all areas using the formula

$$K_{Na} = \frac{\sum N_i a_i - n N_a a_a}{n s_N s_a} \quad (8)$$

where N_a , a_a , s_N , s_a are equal

$$N_a = \sum N_i / n, \quad a_a = \sum a_i / n, \\ s_N = \sqrt{\sum (N_i - N_a)^2 / n}, \quad s_a = \sqrt{\sum (a_i - a_a)^2 / n}. \quad (9)$$

The values of the coefficients A and B were calculated by the formulas

$$B = s_N K_{Na} / s_a, \quad A = N_a - B a_a. \quad (10)$$

The significance of the correlation coefficients for $n-2$ degrees of freedom was determined using Student's T -criterion. The calculated values of this criterion for observation areas PS1, PS2, and PS3 were 31.20, 59.83, and 3.81, respectively, which exceeds the critical value $T_{cr} = 2.01$ and, therefore, allows to present the correlation dependence in the form of a regression equation (7). The

correctness of the use of regression equations is confirmed by a small standard deviation s of the values of N from table 5 from the values calculated using the correlation equations. In the most disadvantageous case, the value of s is about 0.021.

Table 5. Correlation coefficients K_{Na} , critical value T_{kr} , regression coefficients A and B in equation (7) per 1 km² and standard deviation s of the calculation results by formula (7) from the values calculated by formula (5) for individual areas and on average by all areas Σ .

	PS1	PS2	PS3	Σ
K_{Na}	0.997	0.999	0.863	0.970
T	31.20	59.83	3.81	17.35
T_{kr}	2.01	2.01	2.01	1.73
A	-0.010	-0.00058	0.00028	-0.0271
B	0.00221	0.00170	0.00107	0.00225
S	0.0068	0.0014	0.011	0.021

3.3 The distribution of birds by seasons

Analysis of the distribution of birds by seasons was carried out using observational data in winter, in the spring migration period, in the nesting period and in the autumn migration period, shown in Fig. 2-5. The calculations took into account all species of birds recorded in the morning and evening times at all three areas, flying at all altitudes. The correlation coefficient K_{Na} between the calculated number of birds in flight condition and the measurement results in this case is 0.97, Student's criterion at 5% significance level for $n-2$ degrees of freedom $T = 5.94$, critical value $T_{cr} = 2.92$. Since $T > T_{cr}$, the correlation dependence $N(a)$ is significant and the regression equation (7) can be constructed using formulas (10) in the form

$$N = 0.037 + 0.00092a. \quad (11)$$

Comparative data obtained by formulas (5) and (11) are presented in table 6.

Table 6. The average number of recorded birds a in flight condition measured per day and 1 km² and the results of calculating the number of birds N by the formula (5) and N_{Reg} , by the formula (11).

	Winter period	Spring migration	Nesting	Autumn migration
a	99	139	59	130
$K = \sum n_i t_i, c$	11695	26040	11607	22160
N , formula (5)	0.135	0.172	0.090	0.147
N_{Reg} , formula (10)	0.129	0.166	0.092	0.157

In this case, the standard deviation of the experimental values from the values calculated using the regression equation is 0.0069.

3.4 Resume

The Azov-Black Sea coast of Ukraine contains unique steppe plant habitats with numerous populations of migrating birds on the Eurasian scale, therefore the state of biodiversity monitoring on the territory of the wind

power farm is of great importance. The movement of birds in different phases of their life cycle (nesting period, spring and autumn migration, wintering) are significantly different from each other. The largest number of birds were recorded during spring and autumn migrations. The used estimate of the number of migratory birds and their total number at a given time implies monitoring of the observation sites in accordance with the recommendations of the Scottish Natural Heritage Foundation [11]. It is based on the use of formulas (1) – (11), in which the main parameter is the coefficient $K = \sum n_i t_i$.

The value K characterizes the activity of birds presence on the area. Calculation of the K value allows us to estimate the average number of migrating birds N at a given moment of time, not only on this area, but also in the territory adjacent to it.

From general considerations, it is clear that the value of N depends on the movement speed of individuals, their flight trajectory and many other parameters. A statistical analysis of the results of monitoring the territory of the Prymorsk-1 wind power farm showed that in reality it is determined by one integral characteristic by coefficient K . The correlation coefficient between the average number of migrants that are at the observation point and the registered number of birds a crossing this area is estimated by value of 0.97. Moreover, the Student's criterion, which determines the significance of the correlation coefficient, is at least 5.9, which is several times higher than the critical value.

In conclusion, we will carry out a general analysis by combining all the observation results presented in Table (4) - (6). The resulting regression equation has the form

$$N = -0.0105 + 0.00182a. \quad (12)$$

In this case, the correlation coefficient between the number of birds in the air and the counting results is 0.91. The Student's criterion, which determines the significance of the correlation coefficient, is about 10.5, which is more than six times the tabular value of 1.71. A graphical interpretation of the dependence of N on a is shown in Fig. 6. The straight line in this figure is constructed using the regression equation (12), and the points correspond to experimental data.

Fig. 6. The correlation dependence between the measured number of birds a and the number of individuals N currently in flight condition.

The Fig. 6 shows that the experimental points are generally consistent with the regression equation (12). The inaccuracy of using formulas (3) and (5) for

determining the number of birds per square unit depends only on the error in determining the coefficient of birds activity $K = \sum n_i t_i$. This inaccuracy does not exceed 3-5 seconds, which can lead to an error in calculating the parameter K by no more than 5-10%. The main reason for the scatter of points in Fig. 6 is caused not so much by the error in determining the parameter K as by the statistical spread of the recorded data results depending on the season and the selected observation point for accounting.

4 Conclusions

In the work, the behavior of bird ornithological complexes in the territory of the Prymorsk-1 wind power farm in 2017 was studied using the recommendations of the Scottish Natural Heritage Foundation. During the observation, 5923 birds of 45 species were recorded. A statistical analysis of the observation results was carried out and a group of birds at risk zone of collision with turbines of a wind power farm was identified (*Larus ridibundus* – 43 birds, *Merops apiaster* – 15 birds, *Buteo buteo* – 5 birds and *Circus aeruginosus* – 9 birds).

The StatBirds program was developed for statistical analysis of the observation results and a mathematical model for calculating the number of birds in flight condition and on the ground. The number of birds in the territory of the wind power farm was estimated basing on the monitoring results in the winter, spring and autumn periods. According to the calculated data, the average number of birds of all species on the territory of the Prymorsk-1 wind power farm is about 18.8 individuals. Correlation dependencies between the number of individuals in flight state and the number of birds recorded at the observation areas were found.

Environmental monitoring and recommendations on decreasing the levels of pesticide pollution in Zhytomyr region of Ukraine

Olena Uvayeva^{1,*}, Tetiana Vakaliuk², and Dmytro Kostromin¹

¹Zhytomyr Polytechnic State University, Faculty of Mining and Ecology, 103 Chudnivska Str., Zhytomyr, 10005, Ukraine

²Zhytomyr Polytechnic State University, Faculty of Information and Computer Technology, 103 Chudnivska Str., Zhytomyr, 10005, Ukraine

Abstract. Environmental monitoring was conducted of facilities for storage and disposal of banned and unsuitable pesticides. Pesticide content in the soil, water, and products of agriculture in the Zhytomyr region of Ukraine was examined, and the accumulation of organochlorine pesticides by freshwater bivalve mollusks was assessed. Storage facilities of the Zhytomyr region contain nearly 392.18 t of pesticides in 137 warehouses, of which 11 meet the requirements, 36 are tolerable, and 90 are in poor condition. In 2018–2019, pesticide content (dichlorodiphenyltrichloroethane (DDT), heptachlor, dichlorodiphenyldichloroethylene (DDE), dichlorodiphenyldichloroethane (DDD), hexachlorocyclohexane (HCH)) was studied in soil and sediments in the Zhytomyr region. The content ranged from 0.0007 to 0.07 mg/kg, which is lower than MPC (0.1 mg/kg). The content of HCH, DDT, DDE, DDD, and heptachlor was at 0.0007–0.01 mg/dm³ levels in water bodies of the Zhytomyr region in 2018–2019, also lower than MPC. In some samples of soil, water and vegetables, the recorded levels of DDT and organophosphate pesticides Dragon, Dorpan, and Dursban exceeded MPC in 1.5–3.0 times. Traces of organochlorine pesticide Aldrin were found in soft tissues of bivalve mollusks and in the sediments of water bodies they inhabit. Recommendations are proposed to lower the pesticide content in the environment.

1 Introduction

Ukraine has ratified the Stockholm Convention (23 May 2001) with the Law of Ukraine N 949-V (949-16) of April 18, 2007. According to the Convention, persistent organic pollutants (POP) are recognized as toxic, resistant to decomposition, bioaccumulative, and are subject to transboundary movements by air, water and with migrating species. POP is also deposited at a great distance from the source of their emission, accumulating in terrestrial and aquatic ecosystems [1]. By this convention DDT, aldrin, dieldrin, endrin, chlordane, mirex, toxaphene, heptachlor are included in the list of most dangerous substances.

Long-term application of pesticides has led to large-scale environmental pollution over huge territories. The migration of toxic compounds in ecosystems causes the accumulation of residual amounts of pesticides in natural objects.

Organochlorine pesticides (OCP) have been widely used, and some of them still are used in Ukraine [2–7] and other countries [1, 8–14] to control insect pests of agriculture and protect crops. Such as OCP as DDD (dichlorodiphenyldichloroethane), DDT (dichlorodiphenyltrichloroethane), DDE (dichlorodiphenyldichloroethylene), and HCH (hexachlorocyclohexane) are highly persistent, accumulate for a long time in plants, animals, soils, and

are poorly soluble in water. Therefore they usually accumulate in considerable concentration in river sediments and silt.

In Ukraine, OCP has been used most extensively in the 1950–1960s. At the beginning of the 1970s, OCP was shown to be highly toxic to animal organisms. They are also very persistent. DDT does not decompose in the environment for 10 years [6]. When from the environment (soil, water, sediments) OCP enter the living organisms, the compounds circulate in trophic chains of local ecosystems, climbing the trophic levels. Thus, all these components of ecosystems, from producers to consumers of highest levels, contain pesticides in their bodies. DDT and HCH can accumulate in various organs and tissues (in the case of DDT, mostly in fat tissue). OCP is polytropic compounds, thus they are significantly dangerous to human and animal organisms even in small doses. They negatively affect the functional state of the liver, glands, kidneys and other organs. They have also cytotoxic, carcinogenic, mutagenic effects. All this led to the restriction or ban of their use in the early 1970s. But even today, OCP belongs to the category of widespread pollutants both in Ukraine and abroad.

Content of DDD, DDT, DDE, HCH, DDVP (dichlorvos), 2,4-D (2,4-dichlorophenoxyacetic acid) has been analyzed in rivers of Luhynsky district of Zhytomyr region in 1988–2008. The results of the analysis indicated a significant decrease in pesticide content in the two

* Corresponding author: bio-2016@ukr.net

decades [4]. That is linked to the discontinuation of large agricultural enterprises that had used public funds to purchase pesticides. At present, only small farms and private homesteads operate in the district.

The long-term, often uncontrolled and unjustified, use of pesticides in agriculture has led to the contamination of inland water bodies with these dangerous toxicants and the disturbance of natural ecological balance. Pesticides of different chemical origin have a detrimental effect on all representatives of freshwater biota. Due to the cumulative properties, pesticides circulate and accumulate in the organisms of all aquatic organisms, including shellfish. In the early XXI century, several scientists [6] have registered persistent OCP (DDT and HCH) in various organs of six freshwater mollusk species of the family Unionidae in rivers of Zhytomyr and Khmelnytskyi regions.

In the summer of 2008, several pesticides (DDT, DDE, DDD, HCH, aldrin, dieldrin, and hexachlorobenzene) have been found in bivalve mollusks *Colletopterum ponderosum sedakovi* (Siemaschko, 1848) in Lake Baikal [8].

I. A. Fodchenko [7] has found pesticides (DDT, aldrin, HCH, heptachlor) in mussels, produced in Ukraine (the Black Sea coast of Odesa region) and abroad (Chile, China). Pesticides have been found in marine mollusks from other countries: Korea [9], Croatia [11], Italy [12], Asian countries [14] and others.

Today, organophosphate pesticides such as chlorophos, paraoxane, metaphos, carbofos, oxamethyl are used more and more frequently [3]. They are less toxic than OCP and do not withstand water, i.e. they are subject to rapid decomposition, which eliminates their prolonged impact on the biota of reservoirs. Today it is important to monitor both the storage conditions of pesticides, a lot of which are still kept in the Zhytomyr Region of Ukraine [15], and the pesticide content in the soil, water bodies, products of agriculture, and in aquatic organisms.

Study aim: to conduct ecological monitoring of pesticides in the Zhytomyr region and to prepare recommendations on decreasing the pesticide levels in the environment.

2 Material and methods

Study object is pesticide storage warehouses; samples of water, soil and products of agriculture from Zhytomyr region; freshwater bivalve mollusks of the species *Unio crassus* (Retzius, 1783) from Perga river (Radovel' village, Olevsky district of Zhytomyr region) (Fig. 1) and *Anodonta anatina* (Linnaeus, 1758) from Irsha river (Khoroshiv village, Zhytomyr region) (Fig. 2).

The study subject is the ecological monitoring of pesticides in the Zhytomyr region.

The content of pesticides in water, soil, agricultural products and tissues of mollusks was determined based on the State Institution "Zhytomyr Regional Laboratory Center of the Ministry of Health of Ukraine" using standard methods of OCP research, gas-liquid chromatography, and thin-layer chromatography: DSTU EN 1528-1-2002; EN 1528-2:1996; EN 1528-3:1996; EN

1528-4:1996; DSTU EN 12393-(1;2;3):2003; DSTU 4514:2006 [16–18].

Fig. 1. The shell of *Unio crassus* (Retzius, 1783) from the Perha river (Radovel' village of Olevsky district, Zhytomyr region).

Fig. 2. The shell of *Anodonta anatina* (Linnaeus, 1758) from the Irsha river (Khoroshiv village, Zhytomyr region).

Information about pesticide storage was given by the Department of Ecology and Natural Resources of Zhytomyr Region State Administration.

Bivalve mollusks were sampled manually at a maximum depth of 0.5–0.7 m [19]. Most mollusks live on sediments (silt, sandy silt), rarely on sands. Species identification of mollusks was performed based on their conchological features [20].

The results of the study were processed using methods of variation statistics [21].

3 Results and discussion

3.1 The problem of pesticide storage facilities in Zhytomyr region

Numerous warehouses were built in almost all regions of then-Soviet Ukraine to store various types of pesticides (herbicides, fungicides, insecticides, acaricides, zoocides, etc.). Usually, such pesticides are stored in significantly damaged packages, contaminate the soil and seep into the groundwater. Hence, warehouses that contain pesticides are extremely dangerous. They also have no warning signs and are largely unsecured.

One of the acute environmental problems in the Zhytomyr region is the practice of dealing with unsuitable pesticides and agrochemicals. According to the Department of Ecology and Natural Resources of Zhytomyr Region State Administration, 137 warehouses

with unsuitable pesticides and agrochemicals are in the Zhytomyr region, as of 01.01.2018 (Fig. 3). Eleven warehouses meet the requirements, 36 are tolerable, and 90 are in poor condition (Fig. 4, 5). The largest warehouses are located in Yahodynka village (Pulynsky district), with 23.00 tons of pesticides; N. Velidnyky village (Ovrutsky district), with 19.49 tons of pesticides at OJSC “Ovrutsky rajagrokhim”; Koshelivka village (Pulynsky district), with 17.0 tons of pesticides; Veselivka village (Ovrutsky district), with 12.07 tons of pesticides at LLC “Nehodivske”.

Fig. 3. Map of warehouses storing unsuitable pesticides and agrochemicals in Zhytomyr region, as of 01.01.2018: triangle – under 0.5 t of pesticides; circle – 0.5–1.0 t of pesticides; square – more than 1.0 t of pesticides; horseshoe – pesticides were utilized in 2012.

Fig. 4. Pesticide storage in Toporische village of Khoroshiv district, Zhytomyr region (October 2019).

There are a total of 392.18 t of stored pesticides. Of these, 32.450 t are liquid, 24.975 t are solid, and 334.755 t

is unknown mixtures. The condition of the storing containers is as follows: 39.07 t of pesticides are kept in good condition, 22.43 t in satisfactory condition, the rest in poor condition. Due to poor storage conditions, toxic pesticides enter the environment including water and air, presenting the risk of poisoning to humans, flora, and fauna.

Fig. 5. Pesticide storage in Znamianka village of Khoroshiv district, Zhytomyr region (October 2019).

Only warehouses storing unsuitable chemical plant protection products (CPPP) in Berdychiv and Pulyn districts are protected, the rest of the warehouses are not guarded. In the Zhytomyr region, efforts were made of replacing CPPP containers. For example, 33.731 t of unsuitable agrochemicals of the former collective agricultural enterprises were weighed and reloaded in 11 village councils in Korosten district, in October 2014. 37 t of toxic waste were reloaded in sealed containers at the territories of Novovelidnytska, Nevhodivska, Mozharivska and Pokalivska village councils of Ovrutsky district in 2014. Popilnanska united territorial community (UTC) organized reloading at its own expense of 5.5 t of CPPP to sea containers in 13.05.2017.

In 2011–2012, 968.535 t of unsuitable CPPP were reloaded and exported from Ukraine. At present, the territory of Baranivsky, Brusyliv, Lubarsky, Malynsky, Romanovsky, and Ruzhyn districts of the Zhytomyr region has been cleared of CPPP.

Expired pesticides are unusable and must be disposed of. Together with storage packaging, they are hazardous waste that must be correctly deactivated by licensed agencies. Currently, in Ukraine, there are no entities licensed to conduct hazardous-waste management (collection, transportation, storage, treatment, disposal), including unsuitable pesticides.

The problem also lies in the lack of a scientifically sound concept of pesticide processing and deactivation, imperfect technological processes and the incomplete technological cycles of processing, the lack of safe methods of disposal. The whole range of issues related to the elimination or control of the negative effects of toxic waste on the environment and human health will only be effectively resolved with a national program for waste

management.

3.2 Pesticide pollution of soil, water bodies and products of agriculture in Zhytomyr region

According to State Institution “Zhytomyr Regional Laboratory Center of the Ministry of Health of Ukraine”, pesticide (HCH, DDT, DDE, DDD, heptachlor) content was in the range of 0.0007–0.07 mg/kg in soils and sediments of Zhytomyr region in 2018–2019, within the MPC values (0.1 mg/kg) (Table 1).

Table 1. Levels of pollution of soil and sediments with residual amounts of pesticides (mg/kg, MPC = 0.1 mg/kg) in Zhytomyr region (2018–2019).

Waterbody	District	Concentration Pesticide	
		2018	2019

Notes: MPC – maximum permissible concentration; HCH – hexachlorocyclohexane; DDT – dichlorodiphenyltrichloroethane; DDE – dichlorodiphenyldichloroethylene; DDD – dichlorodiphenyldichloroethane; H – Heptachlor; dash – no data available.

In February 2015, an excess of DDT (0.3 mg/kg, MPC = 0.1 mg/kg) was observed in soil sampled at Romaniv village (Makarenko Street) (report No. 1–10 of February 27, 2015). In September 2017, the content of Dragon pesticide (0.29 mg/kg) exceeded MPC of 0.2 mg/kg in soil sampled at the boundary of residential development in the Romanivka village of Brusylivsky district (Centralna str., 1.25 m from the cornfield) (report No. 148–154 of 28.09.2017). The active substance of Dragon is chlorpyrifos. It belongs to organophosphate

compounds. It is a modern, broad-spectrum contact insecticide against sucking and biting insects. It has high initial toxicity, blocking primarily acetylcholine esterase enzymes, which play an important role in the transmission of nerve impulses in insects.

Content of HCH, DDT, DDE, DDD, and heptachlor was measured in water bodies of the Zhytomyr region in 2018–2019 (according to the Zhytomyr Regional Laboratory Center of the Ministry of Health of Ukraine). It fluctuated in the range of 0.0007–0.01 mg/dm³, which is within MPC values (Table 2).

Notes: HCH – hexachlorocyclohexane (MPC=0.02 mg/dm³); DDT – dichlorodiphenyltrichloroethane (MPC=0.002 mg/dm³); DDE – dichlorodiphenyldichloroethylene (MPC=0.002 mg/dm³); DDD – dichlorodiphenyldichloroethane (MPC=0.002 mg/dm³); H – Heptachlor (MPC=0.001 mg/dm³); dash – no data available.

In September 2017, the content of Dragon (0.003–0.004 mg/dm³) and Dorpan (0.003 mg/dm³) pesticides exceeded MPC values (0.002 mg/dm³) in waters of private dug out wells on the Centralna and Shevchenko streets of Romanivka village, Brusylivsky district (report No. 297–301 of 28.09.2017). The active substance of Dorpan is chlorpyrifos, one of the organophosphate compounds. It is a broad-spectrum insecticide.

In August 2016, the content of Dursban pesticide (0.1 mg/kg) exceeded MPC of 0.05 mg/kg in vegetables (zucchini) produced in Yastrubna village of Brusylivsky district (report No. 44 of 4.08.2016). The active substance of Dursban is also chlorpyrifos.

3.3 Accumulation of organochlorine pesticides by freshwater bivalve mollusks

We studied the organochlorine pesticide content in soft tissues of bivalve mollusks of the species *Unio crassus* from the Perha river (Radovel' village, Olevsky district) and *Anodonta anatina* from Irsha river (Khoroshiv village, Zhytomyr region), and also in water and sediments of rivers inhabited by the mollusks. OCP enters the mollusk organisms the same as other pesticides, either through the skin, adsorption with food, or with metabolism. OCP is accumulated most intensively in the body parts of mollusks that are most exposed to the polluted environment (shell, mantle, foot, and branchia).

HCH, DDT, DDD, DDE, heptachlor were not detected in water, sediments, and tissues of bivalve mollusks by gas-liquid chromatography. Thin-layer chromatography

revealed traces of Aldrin pesticide in sediments and soft mollusks (Fig. 6).

Fig. 6. Chromatogram of distribution of organochlorine pesticides on chromatogramic plate “Silufol”, thin-layer chromatography (solvent system hexane, developer silver ammonia, September 2019): A – foot tissues of *Unio crassus* mollusks from the Perha river (Radovel' village, Olevsky district of Zhytomyr region); B – foot tissues of *Anodonta anatina* mollusks from Irsha river (Khoroshiv village, Zhytomyr region), 1 – trace amounts of Aldrin.

Aldrin is a pesticide, used in pest control in plant cultures and against termites. Due to its toxic effect, it is banned not only for use but also for production in Ukraine and many other countries of the world. At the same time, Aldrin reserves may be kept in numerous pesticide storages in Ukraine.

3.4 Recommendations for decreasing pesticide content in the environment

The development of scientific technologies and legislative framework is important in controlling and lessening the negative effects of pesticides on the environment. Hence, the following recommendations are topical:

- the implementation of the Stockholm Convention on Persistent Organic Pollutants in Ukraine should become a matter of national priority;
- there should be scientific studies and development concerned with the determination and monitoring of pesticides;
- system of state monitoring of environment and citizen health under the effect of pesticides should be implemented;
- the infiltration of pesticides into the environment should be limited and/or prevented;
- control should be established over economic entities that produce and sell (or otherwise realize) pesticides, and over citizens or other legal entities engaged in activities related to such pesticides;
- people of Ukraine should be informed of the dangers of pesticides;
- training programs should be developed and implemented on pesticide hazards and their implications for the life and health of humans, the environment, and of alternatives to pesticides;

- illegal circulation of pesticides in Ukraine, circulation of banned and overdue pesticides should be prevented, and areas contaminated with pesticides that are unsuitable or banned to use should be detected and cleared.

4 Conclusions

In the Zhytomyr region, nearly 392.18 t of pesticides are stored in 137 warehouses. The quality of storage containers is as follows: 39.07 t is kept in good condition; 22.43 t is kept in intolerable conditions; other pesticides are stored in containers of poor quality. In 2018–2019, pesticide (HCH, DDT, DDE, DDD, heptachlor) content in soils and sediments of the Zhytomyr region was in the range of 0.0007–0.07 mg/kg, i.e. within MPC values (0.1 mg/kg). Content of HCH, DDT, DDE, DDD, heptachlor in water bodies of Zhytomyr was in the range of 0.0007–0.01 mg/dm³, at the same time, also within MPC. In 2015, DDT content in soil (0.3 mg/kg) exceeded MPC (0.1 mg/kg) in Romaniv village; in 2017, Dragon pesticide content in soil (0.29 mg/kg) exceeded MPC (0.2 mg/kg) in Romanivka village. Also in 2017, Dragon pesticide content (0.003–0.004 mg/dm³) and Dorpan pesticide content (0.003 mg/dm³) exceeded MPC (0.002 mg/dm³ and 0.002 mg/dm³, respectively) in water samples from wells of Romanivka village. In August 2016, Dursban pesticide content (0.1 mg/kg) exceeded MPC (0.05 mg/kg) in sampled zucchinis produced in Yastrubna village of Brusylivsky district, Zhytomyr region. In soft tissues of bivalve mollusks and sediments of the water bodies which they inhabit, residual traces of the organochlorine pesticide Aldrin were found.

Monitoring of trace element content in tap water from Karachuny Reservoir, Kryvyi Rih city

Viktoriia Stoliarenko^{1,*}, Marina Chernova², and Olga Yakovchuk¹

¹Kryvyi Rih State Pedagogical University, 54 Gagarina Ave., Kryvyi Rih, Ukraine

²Public utility “Kryvbasvodokanal”, 6A Jesenina Str., 6A, Kryvyi Rih, Ukraine

Abstract. Control of the trace element content in tap water is particularly important for large industrial regions. The estimation of Cd, Pb, Cu, As, Ni, Zn, Mn, Hg, Se and Co concentration in the tap water of Kryvyi Rih city (Karachuny Reservoir) was accomplished using electrochemical methods, the most popular methods for determining the content of trace elements in natural objects and tap water. A simple and rapid method to determine trace elements in the tap water (Kryvyi Rih city) by inversion-voltammetry has been used. The concentration of trace elements was measured by voltammetric analyzer AVA-2 device that implements the method of inversion voltammetry on a solid rotating electrode made of carbon material. The monitoring of the trace element content in the water of the Karachuny reservoir was carried out on a monthly basis between September 2018 and August 2019. The article presents the obtained voltamperograms of some trace elements, describes content of the trace element in tap water during the year (12 data for each trace element) and analyzes the compliance of drinking water in the city of Kryvyi Rih to the standards and normative indicators of drinking water quality.

1 Introduction

The safety of water supply is one of the main factors of national security of the country. The quality of tap water is carefully monitored at the state level, as the health and life of the population depends on it [1, 2].

Drinking water is intended for human consumption to meet physiological, hygienic, household and economic needs, as well as for the production of products, so its composition according to organoleptic, microbiological, parasitological, chemical, physical and radiation indicators must meet the established hygienic requirements in the State Sanitary and Epidemiological Service of Ukraine 2.2.4-171-10 “Hygienic requirements for drinking water intended for human consumption”. If the water does not meet the standards, it is cleaned and disinfected [3].

Much attention is paid to the quality of drinking water in Ukraine and abroad in the works of such scientists as I. Gushchuk, T. Kotova, I. Andrusishina, A. Serdyuk and others [4-6].

The quality of tap water is monitored with a certain frequency depending on the type of control: complete control – once a year; reduced periodic inspection – once or twice a month; reduced production control from once a month to once a day [1].

The quality of tap water is especially carefully monitored in regions with agricultural and industrial complexes, as typical problems of water quality for them are increased mineralization, hardness, and the presence of harmful impurities. All these consequences of

negative anthropogenic impact on the state of water cause not only the deterioration of the taste of tap water, but first of all make it dangerous for consumption without additional purification measures.

Kryvyi Rih is one of such regions with powerful industrial complex and environmental issues. The water basin of the city has a considerable technogenic loading, which is related to the activities of the main contaminators, including the metallurgical production of “ArcelorMittal Kryviy Rih PLC”, “Pivnichnyi Ore Mining and Industrial Complex PLC”, “KryvbasIron-Ore Complex PLC”, “HeidelbergCement Ukraine PLC” and others.

One of the important components in the composition of water that directly affects the human body are trace elements such as cadmium, plumbum, cuprum, arsenic, nickel, zinc, manganese, mercury, selenium, and cobalt. Some of them are vital microelements for living organisms, as they take an active part in biochemical processes. However, even a slight excess of their maximum permissible concentrations is very dangerous for the human body.

Plumbum has the property to accumulate in the tissues of the body, and it is manifested by the signs of damage of the central and peripheral nervous system, intestines and kidneys. It also blocks enzymes and prevents the formation of vitamins.

Arsenic is very poisonous to humans, causes widespread forms of cancer, and accumulating in the thyroid gland it becomes a cause of endemic goiter. In the case of chronic manganese poisoning, there is

* Corresponding author: st_viki@ukr.net

deterioration in the functioning of the central nervous system, changes in functions in the cardiovascular system, esophagus and liver.

Zinc is a very important trace element that acts as a cofactor of about 300 enzymes and it is an immunostimulator, but exceeding the permissible norms causes acute forms of poisoning. Cadmium is a very toxic element for the human body and it has the ability to accumulate and to affect the liver and kidneys, and this element is carcinogenic.

Cuprum is a part of important enzymes and proteins and it promotes growth and development of the human body, participates in hematopoiesis, and immune responses. Excessive intake of cuprum in the body causes bronchial asthma, kidney disease, liver disease, and intoxication.

Nickel is a part of some proteins, RNA and DNA, and its excess has a toxic and carcinogenic effect. Cobalt is a part of vitamin B₁₂, takes part in the processes of hematopoiesis. The excess of cobalt causes dermatitis, cardiovascular failure, and affects the respiratory system. Mercury affects the cardiovascular and nervous systems and kidneys.

Selenium is part of many biologically active compounds, participates in the regulation of metabolism, metabolism of fats, proteins and carbohydrates, as well as in oxidation-reduction processes. Selenium overdose can damage the respiratory, excretory and nervous systems [7-10].

Therefore, the significant impact of trace elements on the human body makes it important to systematically control of their content in the environment, in particular, in tap water and further purification of water from excess trace elements if it is necessary.

2 Materials and methods. Gathering samples

Voltammetry is one of the most popular methods for determining the content of trace elements in natural objects and drinking water, which is associated with the ability to detect low concentrations of elements using this method with high accuracy [11-14]. In order to determine the content of trace elements in drinking water from the Karachuny Reservoir it was used the method of inverse voltammetry.

2.1 The essence of the method of determining trace elements

The inversion-voltammetric method is based on the ability of an element to be analyzed electrochemically to accumulate on the surface or in the volume of an indicator working electrode and to dissolve in the process of anodic or cathodic polarization at a specific potential characteristic of each element.

The peak height of the element registered on the voltammogram is proportional to the mass fraction of the element in the solution.

The content of trace elements in drinking water samples is determined automatically by processing the

values of the element's analytical signals on voltammograms of a series of solutions.

2.2 Device

The concentration of trace elements was measured by voltammetric analyzer AVA-2 from Research and Development enterprise "Byrevestnik".

The AVA-2 analyzer is an electrochemical device that implements the method of inversion voltammetry on a solid rotating electrode made of carbon material.

The measuring cycle of the AVA-2 voltammetric analyzer includes four stages:

- the first stage – electrochemical regeneration of the surface of the working electrode (potential from 0 to +650 mV);
- the second stage – the electrochemical accumulation of trace elements on the surface of the working electrode (potential from 0 to -1500 mV);
- the third stage – sedation of the solution (potential from 0 to -1500 mV);
- the fourth stage is measurement, the current-potential curve is built and recorded (potential from 0 to -1500 mV).

The current-potential dependence is recorded in the form of a graph in which the position of the current peaks on the potential axis qualitatively characterizes the trace elements which is determined (each element has its own dissolution peak). The height of the peak is proportional to the concentration of trace elements in the solution.

The AVA-2 analyzer measures the concentration of metal ions in aqueous solutions in the range, mcg/dm³: 0,005-100 (Hg); 1-10000 (Zn); 1-200 (Pb, Cd, Cu); 1-1000 (As).

Sensitivity limit, mcg/dm³ – 0,01 (Cd, Pb, Cu, Zn); 0,2 (As), 0,005 (Hg).

2.3 Reagents and Technique

2.3.1 Reagents

All of the used reagents were of purest quality possible (analytical grade).

Before use, distilled water was further purified by distillation with an alkaline solution of potassium permanganate.

2.3.2 Technique

The standard technique measurements of the mass concentration of toxic metal ions in drinking and surface water by inversion voltammetry was chosen for the experimental determination of the trace elements cadmium, plumbum, cuprum, arsenic, nickel, zinc, manganese, mercury, selenium and cobalt in the tap water from the Karachuny Reservoir [15].

The standard additive method was used to determine the mass concentration of element in drinking water samples. This technique measurements does not require

a calibration schedule.

The method of standard addition is based on the detection of cycles voltamperograms for the same measurement parameters of a series of three solutions:

- 1) background electrolyte (background);
- 2) sample prepared for measurements;
- 3) the same sample into which the solution-additive of the measured element is introduced, with a known mass concentration.

The volume of the additive solution depends on the content of the element, which is determined in the sample. It is added in such an amount that the height of the characteristic peak of the solution with the additive has to increase in 2-3 times in the sample with the added additive solution (solution 3) in comparison with the height of the peak in the experimental solution (solution 2).

The additive solution can be administered several times, but the total volume should not exceed 10% of the sample volume analyzed.

The result of three measurement cycles is a voltammogram, which determines the quantitative content of the trace element in solution.

Characteristic potential peaks for trace elements in voltammograms:

- Peak potential (Zn) -1150...-800 mV
- Peak potential (Cd) -600...-450 mV
- Peak potential (Pb) -450...-300 mV
- Peak potential (Cu) -150...-20 mV
- Peak potential (Mn) -1550...-1450 mV
- Peak potential (Hg) 450...650 mV
- Peak potential (As) -100...300 mV
- Peak potential (Ni) 1090...1180 mV

2.3.3 Gathering samples

The main source of tap water in Kryvyi Rih is the Karachuny Reservoir. The monitoring of the trace element content in the water from the Karachuny reservoir was carried out on a monthly from September 2018 to August 2019.

Selection, storage and handling of drinking water samples were performed in accordance with DSTU ISO 5667-6 and DSTU ISO 5667-3.

3 Results and discussion

The content of trace elements in tap water from the Karachuny Reservoir (Kryvyi Rih) was evaluated using inversion voltammetry method.

During the experiment, three consecutive measurements were made for a sample of drinking water for each element. According to the received voltammograms, the presence of a certain trace element and quantitative characteristics of its content were determined in the sample. Figures 1-2 show the voltammograms obtained for zinc and plumbum (voltage (v) with the current (a)).

The resulting voltammograms contain three curves in the coordinates voltage (V) with the current (A), which are indicated by different colors.

Fig. 1. Voltammogram of the trace element Zn in tap water.

Fig. 2. Voltammogram of the trace element Pb in tap water.

The black curve reflects the value of the background solution. Red curve corresponds to the sample of the water under being tested. Blue curve corresponds to the water sample that is being investigated with the added solution-additive.

The content of trace elements in the samples of the studied tap water was calculated by automatic processing the analytical signals of the element on voltamperograms in a series of solutions. The established data of the trace elements content in tap water from the Karachuny Reservoir are presented in four tables according to the season of autumn, winter, spring and summer (Table 1–4).

Table 1. Concentrations of essential trace elements in Karachuny Reservoir (autumn 2018).

Elements	Concentrations of trace elements in $\text{mg/dm}^3 \pm \text{S.D.}$		
	September	October	November
Mn	$2,3 \cdot 10^{-2} \pm 1,5 \cdot 10^{-3}$	$2,6 \cdot 10^{-2} \pm 3,1 \cdot 10^{-3}$	$2,1 \cdot 10^{-2} \pm 1,5 \cdot 10^{-3}$
Cu	$6,8 \cdot 10^{-3} \pm 2,6 \cdot 10^{-4}$	$8,1 \cdot 10^{-3} \pm 3,8 \cdot 10^{-4}$	$7,8 \cdot 10^{-3} \pm 7,0 \cdot 10^{-4}$

The results obtained in the autumn months showed a high concentration of manganese in water relative to concentration of other trace elements; the lack of detectable amounts of cadmium and low constant values for cobalt and selenium.

The trend in the distribution of trace element concentrations that was established for the autumn period repeated in the results of studies of the trace elements content in drinking water in the winter months again. And it did not change significantly in the data obtained in spring and summer studies.

In this way, monitoring of the trace element content in tap water showed that manganese, cuprum, zinc, arsenic, mercury, plumbum, nickel, cobalt and selenium were present in the tap water samples, but the concentrations of these elements were lower than the maximum levels at State Sanitary Rules and Regulations (Table 5). Cobalt and selenium were found in concentrations that were low enough for these elements. Cadmium was not in all samples or it was in quantities below the capability of the instrument used.

Figure 3 and figure 4 show the monitoring of trace elements in tap water from the Karachuny Reservoir in the period from September 2018 to August 2019.

The concentration of manganese in drinking water is the highest among all trace elements that have been studied. One of the main reasons for the increase in the

manganese content in the natural waters of industrial regions is the technogenic pollution of water by industrial wastewater. This is a typical situation for industrial regions such as Krivorozhsky district. However, the concentration of manganese in the drinking water of Karachuny Reservoir does not exceed the maximum permissible concentration for this microelement ($0,005 \text{ mg/dm}^3$) and stays in the range $1,6 \cdot 10^{-2} - 3,5 \cdot 10^{-2} \text{ mg/dm}^3$.

Table 5. The intervals of concentrations of trace elements in tap water during the autumn of 2018 – summer 2019.

Name of trace elements	Standard of the permissible limits of trace elements, mg/dm ³	Concentrations of trace elements in mg/dm ³	
		max	min
Mn	$\leq 0,05 (0,5)^1$	$3,5 \cdot 10^{-2}$	$1,6 \cdot 10^{-2}$
Cu	$\leq 1,0$	$9,7 \cdot 10^{-3}$	$5,8 \cdot 10^{-3}$
Zn	$\leq 1,0$	$3,7 \cdot 10^{-3}$	$2,7 \cdot 10^{-3}$
Cd	$\leq 0,001$	-	-

Fig. 3. Concentrations of trace element Mn in Tap water from Karachuny Reservoir.

Fig. 4. Monitoring of trace element content in tap water from Karachuny Reservoir.

Changes in concentrations of trace elements Cu, Zn, As, Hg, Pb, Ni during the year are shown in Figure 4.

There are no curves that showed the content of trace elements Cd, Co and Se in drinking water which is under study on the figure 4, because the presence of cadmium

was not established by this method of study, and selenium and cobalt gave as a result low permanent data in their determination.

As shown in the figure 4, the concentration maxima for most trace elements occur in the spring season. The reason may be the ingress of polluted melt water and industrial emissions into Karachuny Reservoir during this period.

Trace elements Zn, Co and Se were founded in fairly low concentrations in drinking water. Their reduced content in water can lead to increased accumulation of iron, copper and cadmium in the human body and to frequent colds and infectious diseases [8, 16-18].

The reliability of the obtained results was verified using statistical methods of analysis with the calculation of such elementary mathematical statistics as the sample mean variance, standard deviation (Table 1-4), confidence interval, limits of confidence interval (Table 6).

*09 – 12 months 2018 year, 01-08 months 2019 year

Statistical analysis of the monitoring results showed the absence of gross errors in the statistical sample data, all the values of the successive measurements are within the confidence interval. Therefore, the established

content of trace elements in water samples can be considered close to true.

4. Conclusions

Monitoring of trace elements in the tap water from the Karachuny Reservoir showed that the content of any trace element that was selected for the study did not exceed the maximum permissible concentration during the year.

For trace elements of manganese, plumbum and cuprum, a noticeable fluctuation of the content was observed. Maximum values were fixed for manganese in April ($3,5 \cdot 10^{-2}$ mg/dm³) and August ($3,4 \cdot 10^{-2}$ mg/dm³); for cuprum ($9,7 \cdot 10^{-3}$ – $9,5 \cdot 10^{-3}$ mg/dm³) and plumbum ($8,0 \cdot 10^{-3}$ – $8,2 \cdot 10^{-3}$ mg/dm³) in March.

Minimum values were fixed for manganese in December ($1,6 \cdot 10^{-2}$ mg/dm³); for cuprum ($5,8 \cdot 10^{-3}$ mg/dm³) and plumbum ($2,6 \cdot 10^{-3}$ – $2,9 \cdot 10^{-3}$ mg/dm³) in June-August.

The content of other trace elements was changing more smoothly and remained about an average value during the year. The average annual concentrations of these trace elements in water which was under study were: Zn – $3,24 \cdot 10^{-3}$ mg/dm³; As – $3,87 \cdot 10^{-3}$ mg/dm³; Hg – $3,2 \cdot 10^{-4}$ mg/dm³; Ni – $6,28 \cdot 10^{-3}$ mg/dm³.

Thus, drinking water in Kryvyi Rih in terms of the trace elements content of cadmium, plumbum, cuprum, arsenic, nickel, zinc, manganese, mercury, selenium and cobalt meet the normative requirements for the quality of drinking water and they are safe for human consumption.

However, the low content of trace elements zinc, cobalt and selenium in drinking water makes its quality worse. People should use other ways of delivering these trace elements to the body (a varied diet, vitamin complexes).

Environmental aspects of petroleum storage in above ground tank

Amgad Fathey Fayek Tadros*

Petroleum Pipelines Company, Mostorod, PO Box 1104, Cairo, Egypt

Abstract. Oil pollution is a severing global environmental problem causing a number of adverse negative impacts on human health air ecosystem and eventually the natural income that is why soil, water, air pollution with petroleum hydrocarbons have become the focus of increasing public and research concern petroleum hydrocarbon contaminants in the air environment are caused by human activities when harmful or excessive quantities of substances are introduced into Earth's atmosphere. Sources of air pollution include gases such as carbon monoxide, sulfur dioxide, hydrogen sulfide, methane, the aliphatic and polycyclic aromatic hydrocarbons (PAH's) fractions of petroleum are readily evolved to air during refinery and choosing the wrong storage tanks also leak to the soil change the chemical composition of spilled toxicity and biological impacts of the oil and add great difficulties to the identification of the residual spilled oil in the impacted environment and economic cost of air pollution in illness, health care costs, lost productivity so coordination between humans to conserves natural resources for future generation.

1 Introduction

Nowadays, energy is recognized as one of the main factors to the formation and development of industrial communities. The importance of Oil and petroleum is highlighted as their basically role at human life. Egypt has major importance at this field due to great capacity of energy resources, especially oil and gas, and also special geopolitical position. On the other hand, during recent year's oil products has decreased because of growing population and increasing demand to oil products and decreasing of crude oil extraction at compare to export.

However, to achieve suitable levels of production, the use of improved technologies should be considered via introducing new facilities that treat the crude oil sulphur and nitrogen to be stored in tanks with minimal pollution to the surrounding environment, another way to save oil products and prevent the evaporation loss or leakage by construction of storage tanks according to standard codes and preferred to be stored in floating roof tanks.

Evaporation of hydrocarbons and their products from on the above ground storage tanks has been of special concern in the recent years. Emissions from storage tanks are responsible not only for a depletion of the product supply but also for contributions to atmospheric air pollution.

Storage tank of hydrocarbons are important evaporation source of volatile organic compounds (VOC) and nonorganic gases such as carbon monoxide and hydrogen sulphide, etc.

In the present investigation the methods of

hydrocarbon evaporation calculation are studied and measurement of pollution. Subsequently hydrocarbon evaporation and air pollution are computed and measured from Project Consulting Group (PCG) faculty of engineering Cairo university. All necessary parameters which influence evaporation from storage tanks are measured and types of polluted gas evolved are measured. Estimation of the pollutions of oil products from storage tanks requires comprehensive information. the required data has been provided to Arabian oil pipelines company and provide oil products.

The aim of the site to collect, distribute and products are transported under pressure through a pipeline 20" length 84 km connected to Petroleum Pipeline Company which own a network of pipelines located throughout Arab Republic of Egypt, the Arabian oil pipelines company. The site are compromised of loading arm shed for charging (shipping), the oil trucker with different type of oil products like (gas oil and gasoline and kerosene) and two pumps shed. The pump shed a composed of main pumps and booster pumps are used to transportation via pipelines and storage tanks or vice versa to other oil firms using pipelines the other pump shed (B) composed of shipping pumps and two circulation pump and firefighting pump shed has diesel pumps and jockey pumps. There is measurement of chimneys of diesel pumps to monitor.

The level of SO_x and NO_x and reducing it as possible finally 12 tanks, including six fixed roof and four floating roof tanks and two double roof tanks. The tanks are contained fuel oil, Gasoline and Kerosene. Ten tanks are active and one of them is under overhaul.

The cylindrical tanks are with diameter of 44 meters

* Corresponding author: chem_amgad_ppc@hotmail.com

and height of 14.64 meters. This software is designed to estimate evaporation from organic liquid storage tanks and need to specific information about tank (dimensions, construction conditions and color ...), type of liquid (chemical components and liquid temperature ...) and position of the tank (nearest city, temperature and ...) to present the evaporation from these tanks to the air.

Final reports are included monthly and annual emission for each petroleum product or combination of chemicals is stored in the tank. Evaporation rate is considered from three tanks with number one, five and six, respectively containing diesel gas oil, gasoline and kerosene. Then the observed results were used to estimate emission values from the other storage tanks.

According to software results, the estimation of annual evaporation from a gas oil tank is about 2.9 tons per year that the 2.1 tons evaporation is in operation conditions and 0.8 tons evaporation is in static conditions.

There are the other three gas oil storage tanks, so the total emission of fixed roof storage tanks containing gas oil is about 8.7 tons per year. Three storage tanks contain gasoline. Because of gasoline is very volatile and the evaporation rate is noteworthy, tanks with floating roof is used to minimize environmental pollution it's consider environmentally friendly with concern to code during construction to avoid the leakage to soil.

Annual evaporation rate of the tanks with floating roof is 33.3 ton per year. Four storage tanks were contained kerosene. These tanks have floating roof. Annual evaporation rate of the one reservoir is about 0.5 ton, so total annual evaporation of the tanks is 2 tons per year. The present estimations show annual evaporations of about 8.7, 33.3 and 2 tons of Gas oil, Gasoline and Kerosene from Arabian oil pipelines storage tanks respectively. Therefore, such evaporation can have adverse effect on the air quality of surrounding areas. In view of economical aspects such losses Implementation of simple energy savings and as color of tanks, inner condition of shell and type of primary and secondary seals can reduce evaporation Gas oil, Gasoline and Kerosene from 8.7, 33.3 & 2 ton/yr to 6.9, 9.1 & 0.4 ton/yr respectively.

We also recommend continues monitoring of storage tanks for any probable losses and minimization of polluted gas to the surrounding environment. In the future, it is suggested using cone shaped roofs while selecting among various fixed roofs.

Also, it is more logic to make use of primary and secondary seals in floating type roofs. The corrosion of inner surface of storage tanks must be controlled at minimum possible to protect soil and water supply resources if the tanks are constructed beside river or sea. It is also recommended to use white color throughout the outer surface of storage tanks.

2 Environmental management of petroleum storage tank systems

The exploration and exploitation activities of petroleum industry often causes environmental degradation that

have significant impact on quality of air water soil vegetation and on health unless adequate preventive measures are planned.

To protect the natural environment, specifically air and soil and the water resources, from adverse effects that may result as a consequence of operating storage tank systems. This includes avoiding the contamination and negative ecological impacts from potential leaks and spills, and/or fires and explosions resulting from the release of petroleum products and/or allied petroleum products.

To mitigate the potential financial impacts, particularly due to spills and leaks as a result of the regular operations of storage tank systems at this industry, facilities, Community, and other buildings. That operate storage tank systems (all of the above will be referred to in this directive as institutions) to ensure that petroleum storage tank systems are operated, maintained and monitored.

3 Environmental impacts of petroleum storage in above ground tank

Petroleum industry take several steps via drilling the oil will followed by storage in tank crude oil then refinery and storage the products from the refinery process are also major contaminators of surface and ground water by leaking through the soil. The deep wells for the disposal of waste material end up in aquifers and ground water. Some of the refineries also discharge untreated waste material into the water bodies such as lakes and rivers. This means of waste disposal into the rivers affects the quality of water and the water animals. The petroleum products that find their ways into the water bodies are also highly inflammable and may cause river fires like has been the case of Cuyahoga River. Petroleum refining activities may also contaminate the soil.

Soil contamination includes the hazardous waste, oil spills, sludge from the treatment process, and coke dust. Soil contamination reduces the fertility of the soil and introduces foreign particles which may affect the growth and quality of crops.

One of the environmental impacts that may arise out of the implementation and operation of the storage tanking is oil spill and evaporization of products polluted the area each activity involves in the operation of tank farm has a potential spill risk and evaporization of different types of gases causing pollution.

3.1 Chemicals

They are also a major source of criteria air pollutants: sludge, nitrogen oxides (NO_x), carbon monoxide (CO), hydrogen sulfide (H_2S), and sulfur dioxide (SO_2). Refineries also release hydrocarbons such as natural gas (methane) and other light volatile fuels and oils.

Storage tanks also release fewer toxic hydrocarbons such as natural gas (methane) and other light volatile fuels and oils. Petroleum facilities including refinery and storage of crude oil and different products after the refinery process is a major source of pollution in areas

where they are established. The entire process are major sources of toxic air pollutants including BTEX compounds, carbon monoxide, particulate matters, and sulfur dioxide. Some of toxic chemicals released into the air are suspect cancer-causing agents and are also responsible for the development of reproductive problems, and respiratory complications. A large amount of carbon monoxide emissions traps the heat in the earth leading to climate change.

3.2 Measurements

Standards used in performing tests: Multi gas monitor IR; Particulate monitor testo. Some characteristics of the equipments used in the study are given in Table 1.

The results of Table 3 and Table 3 are applicable only for the environmental conditions during the measuring process:

- Temperature 25.3 ± 2 C;
- Relative Humidity $24 \pm 3\%$.

Calibration certificate. Description Gas analyzer CO₂:

- Range: 0-5%;
- Manufacturer: GFG, Model: G460II;
- Accuracy: 2%;
- Environmental condition: 20°C.

Basis of test the instrument has been calibrated by using multi gas dilution system traceable to SI units, according to EPA method (EPA-454 / B-13-003) (see Tables 4 and 5).

Multi gas monitor device conduct chemical analysis on sample streams to flow from the process equipment into an analyzer sometimes conditioning the sample stream in between such as reducing pressure or changing

the sample temperature is widely used for atmospheric air analysis, including applications for healthcare and environmental monitoring moreover these devices enable high throughout real time monitoring. These tests

are applied using devices such as (RAE) and (Gas alert micro 5) and (Microtector G460II) is the most advanced portable chemical detector. With the flexibility of up to six gas sensors, this multi-gas monitor is versatile and customizable, while delivering real-time access to instrument readings and alarm status from any location. These devices contain an electrical pump that withdraws air sample that detects the presence of gases in an area during the refinery or storage in petroleum tanks; it can detect

combustible and toxic and flammable and oxygen depletion. These detectors' technology are combustible gas sensor, photo ionization detector (PID), infrared sensors, electrochemical gas sensors, the electrical pump withdraws air sample to be analyzed and it depends on the detection type. The detectors' types (PID) is a portable vapor and gas detector that detects a variety of organic compounds.

Table 3. Measured parameter: Air pollutants concentration from chimneys measurement (SO₂, NO_x, CO).

Location name	Variables	Mean value	Expanded uncertainty	Limit as law no .(9) for year 2009 indicates as amend for the year 2011	Evaluation
Generator	CO (milli gm/m ³)	120.3	±11.9	250	Accepted
	SO _x (microgm/m ³)	350.4	±24.1	1300	Accepted
	NO _x (microgm/m ³)	392.4	±31.4	500	Accepted
Firefighting diesel pump	CO (milli gm/m ³)	158.3	±13.2	250	Accepted
	SO _x (microgm/m ³)	450.4	±26.8	1300	Accepted
	NO _x (microgm/m ³)	421.4	±29.4	500	Accepted

Photo ionization occurs when an atom or molecule absorbs light of sufficient energy to cause an electron to leave and create a positive ion. The PID is comprised of an ultraviolet lamp that emits photons that are absorbed by the compound (bombardment of air sample) in an ionization chamber. Ions (atoms or molecules that have gained or lost electrons and thus have a net positive or negative charge) produced during this process are collected by electrodes.

The current generated provides a measure of the analyte concentration. Because only a small fraction of the analyte molecules are actually ionized, this method is considered nondestructive to measure volatile organic compounds and other gases in concentrations from sub parts per billion to 10 000 parts per million. The other type of sensor, electrochemical, used for detecting oxygen and toxic gases.

More specifically, they measure the concentration of a specific gas within an external circuit. This is done by method of oxidation or reduction reactions. These reactions generate the positive or negative current flow through said external circuit. The third type, Microtector G460II.

Use IR sensor for (O₂, H₂S, CO, CO₂ and combustible gases, in particular, NO₂, SO₂ and a variety of other gases) and combustible gases (LEL and 100% vol.) for a non-toxic atmosphere.

Measures trace gases by determining the absorption of an emitted infrared light source through a certain air sample. The reported expanded uncertainty values are based on a standard uncertainty multiplied by a coverage factor ($K=2$), providing a level of confidence of approximately 95%. The uncertainty evaluation has been carried out in accordance with (UKAS) requirements.

The standards used to perform this test are traceable

to standard defined and maintains and disseminated by the (NIS) or other international standards organization or have been derived from accepted values of natural physical constants.

The result shown in this report is applicable only for the environmental conditions during the test itself.

Table 4. Calibration result Gas analyzer CO₂ G460II.

0.5	0.51	0.01
1	1.05	0.05
2	2.3	0.3
3	3.3	0.3

Fig. 1. Calibration chart of Gas analyzer CO₂ G460II.

The calculated uncertainty = ±2.839%.

The reported expanded uncertainty is based on a standard uncertainty multiplied by a coverage factor.

Description gas analyzer (SO₂):

- Range 0-20 ppm;
- Manufacturer: CFG, Model G460II;
- Accuracy: 2%;
- Temperature 20°C;

– Humidity: 62.9%.

Basis of test: the instrument has been calibrated by using multi gas dilution system traceable to SI units and according to EPA method (EPA-454/B-13-003).

Table 5. Calibration result Gas analyzer SO₂ G460II

Applied values SO ₂ (ppm)	Reading values SO ₂ (ppm)	Error SO ₂ ppm
0	0	0
3	3	0
5	5	0
8	8.1	0.1
10	10.1	0.1

Fig. 2. Calibration chart of Gas analyzer SO₂ G460II.

The calculated uncertainty = $\pm 2.83\%$.

The reported expanded uncertainty is based on standard uncertainty multiplied by a coverage factor $K=2$ providing a level of approximately 95%.

From the results of previous measurements, it is clear that all the results of measurements comply with environmental law no. (9) of 2009 and the amendments for the year 2011.

4 Results and discussion

To decrease pollution potential, place tanks within a secondary containment structure consisting of a dike and a pad. All piping should be above ground within the dike or may go over the dike wall.

However, if it goes over the dike wall, it must be placed below the ground and within 10 feet of the dike wall. Above-ground piping must be made of steel and coated to prevent corrosion. Any below-ground piping may be either steel or fiberglass, but the steel piping must be coated and cathodically protected, floating roof tank are preferred to prevent vaporization of gases which are responsible for pollution, spill protection usually consists of a catch basin for collecting spills when the tank is filled. Overfill protection is a warning device such as a buzzer or a prevention device such as an automatic shutoff. These precautions can prevent a number of small releases over time from polluting ground water.

Installation of flame arrestor and breathings valves to guarantee the safety of the tanks to avoid petroleum fires which lead the pollution to the environment with different kind of gases and toxic gases to control the air pollution and treatment of crude oil during the refinery process to eliminate the inorganic and organic contaminant especially sulfur to reduce the air pollution,

monitoring the storage tanks with multi gas detector to evaluate the percentage of harmful gases and polluted gases to atmospheric air.

Abstract. Object of research: to systematize (taking into account the possible consequences to biosphere) the known technologies for ecological restoration of soils contaminated by heavy metals and radionuclides. Only a healing technology should be recognized as one possible methodology for solving any soil problems. For soils contaminated by heavy metals and radionuclides healing patterns is conceptually ordered into the following levels: mission, strategy, technology. The mission of healthy soil should be aimed at maintaining the chemical elements content within the optimum interval. The strategy of healthy soil involves the regulation of individual elements content in the soil. Ex-situ a soil healing technology is implemented outside the original pollution site. In-situ, a soil healing technology is carried out directly on the original pollution site. Excavation of the contaminated soil layer is the first stage for ex-situ soil restoration. In the future it will be possible: 1) storage of contaminated soil at special landfills, 2) treatment of contaminated soil at a special reactor. All technologies for in-situ healthy of heavy metals contaminated soils can be ordered as: 1) localization, 2) deconcentration, 3) inactivation, 4) extraction.

1 Introduction

Soil, as an indispensable component of the biosphere, plays a crucial role in solving the problem of Human & Nature interaction. It is the soil, as well as its unique ecological properties that shape the conditions and provide the means of existence for human civilization [8, 20, 30, 34, 43].

The large accumulation of pollutants in soils is the most urgent task for modern soil science. Among the soil pollutants, heavy metals and radionuclides are the most dangerous to human health. On the 21st century, the total area of contaminated land by these political agents is estimated in millions of hectares. In soil the heavy metals' half-life is hundreds and thousands of years, and the radionuclides' half-life is tens and hundreds of thousands of years [21, 24, 28, 38, 44]. That's why, multiple studies were performed to technology development for cleaning the soil, contaminated with heavy metals and radionuclides. However, the proposed contaminated soil cleaning technologies have a clearly anthropocentric character [1, 4, 23, 26, 45].

At the same time, possible consequences for living organisms and soil from a new technology for a contaminated land restoration introduction were left without due attention [3, 18, 24, 36, 46].

Object of research: to systematize (taking into account the possible consequences to biosphere) the known

technologies for ecological restoration of soils contaminated by heavy metals and radionuclides.

2 Materials and methods

As the materials of this work were used: 1) own long-term research results; 2) modern scientific publications, which contain: a) real achievements in soil ecology / biospherology, b) data on successful technologies for restoration / purification / rehabilitation of soils contaminated by heavy metals and radionuclides.

In this work, research methods such as analysis and synthesis, induction and deduction, analogy and formalization, abstraction and concretization, classification and modeling were used.

3 Results and discussion

We believe that the concept of sustainable development is the main paradigm for modern soil science. However, for the successful implementation of this concept in soil science, soil must be considered as: 1) the object of production, 2) a component of the human habitat, 3) the functional of the biosphere.

3.1 Principal model of the healthy soil

We believe that, the known and tested technologies for restoration of contaminated soil have exclusively

* Corresponding author: savosko1970@gmail.com

anthropocentric character. Since in most cases, they are aimed at solving the problems of society – the negative consequences for humans of the excessive pollutants content in soils to reduce. Whereas, modern technologies for restoration of contaminated soil should be based solely on the principles of pedosphere.

Therefore, the one possible methodology for solving any soil problem should be recognized only as a healing technology. As applied to heavy metals and radionuclides, soil improvement should include 1) elimination of negative consequences for the biosphere and humanity from the presence of these pollutants in soils, 2) unconditional preservation of soil functioning parameters within the limits of naturally acceptable norms. It is important to clarify that in solving any environmental problem, ignoring the conservation of soil health is possible only in exceptional cases (for example, the presence of a direct threat to human health). However, after eliminating the negative consequences of the soil pollutants action, measures are necessary for a soil properties and soil health regeneration.

In our opinion [27, 28, 29, 30, 48] for soils contaminated by heavy metals and radionuclides healing pattern is ordered conceptually into the following levels: mission, strategy, technology. The mission of healthy soil should be aimed at maintaining the chemical elements content within the optimum interval. The strategy of healthy soil involves the regulation of individual elements content in the soil. With a lack of certain metals (as nutrients), it is advisable to add metals to the soil (as fertilizer). With excessive content of heavy metals and radionuclides in the soil, it is necessary to eliminate and / or limit their negative impact on soil, biota, farm animals and humans. It must be emphasized that soil healing technologies involve of two measures implementation, which vary in location. In the first case (ex situ) a soil healing technology are implemented outside the original pollution site. In the second case (in situ), a soil healing technology are carried out directly on the original pollution site.

3.2 Ex situ healthy of contaminated soil

Excavation of the contaminated soil layer is the first stage for ex-situ soil restoration (Fig. 1). For this purpose, only the upper soil layers (0-5 cm, maximum 0-20 cm) are usually removed, since in these soil layers a prohibitive heavy metals / radionuclide content was usually [2, 5, 7, 11, 49].

In the future, two systems of activities can be implemented. The first technology is the storage of contaminated soil at special landfills. The second technology is the treatment of contaminated soil at a special reactor.

Storage of contaminated soil can be performed: a) with preliminary treatment by special reagents that reduce the mobility of pollutants in the soil (lime, phosphogypsum, carbonates), b) without preliminary treatment [6, 9, 15, 19, 47].

The technology of storing contaminated soil, as a method of healing contaminated lands, has numerous applications in world practice. However, this technique does not solve the problem of the presence of pollutants in the soil, but only “preserves it.” That is why the widespread use of the storing heavy metals contaminated soil method is inappropriate. However, exceptions are possible – in limited areas, which are of very great importance. While for radionuclides, most likely this is the most likely way to improve excessively contaminated soil.

As we noted earlier, the second technology is the treatment of contaminated soil at a special reactor. In our case, only metals can be removed, therefore this method is called “demetalization”. For this purpose, it was used [30]: 1) physical (hydrocyclonation, separation by density gradient, sonication), 2) chemical (washing with reagents, flotation), 3) physicochemical (electrochemical leaching), 4) biological (microleaching) techniques for contaminated soil demetallization (Fig. 1).

According to scientific literature data [10, 13, 25, 49, 51], soil demetallization technologies are characterized by: 1) a high degree of metal recovery (in some cases up to 95-95%); 2) low productivity of installations (from 10 to 300 tons of soil per day); 3) the high cost of cleaning (100-450 USD per 1 m³ of soil). It is also necessary to note that a soil that has undergone a full treatment cycle often loses a number of its leading properties. Therefore, after contaminated soil demetallization it is very necessary to apply techniques to restore soil fertility. Only after this, the cleared soil can be returned to its former place of residence.

3.3 In situ healthy of contaminated soil

3.3.1 *Environmental healthy of metals' contaminated soil*

In our opinion, all possible technologies for in-situ healthy of heavy metals contaminated soils can be ordered as: 1) localization, 2) deconcentration, 3) inactivation, 4) extraction (Fig. 2).

Localization is a technology that involves spatial limitation to increase the area of pollution. Localization has three directions: 1) phytolocalization, 2) technolocalization, 3) chemolocalization [30, 50].

Phytolocalization involves limiting the distribution of metals as a result of creating an artificial vegetation cover: grassy or woody. At the same time, the success of phytolocalization is determined by the combined action of two factors: the edaphic conditions of the contaminated area, and the selection of plants. To increase the efficiency of phytolocalization, it is recommended to use several ameliorants.

Technolocalization involves limiting the spread of metals from contaminated areas using mechanical barriers. At the same time, depending on the location and technology of creating such barriers, there are: mulching and the formation of techno-curtains.

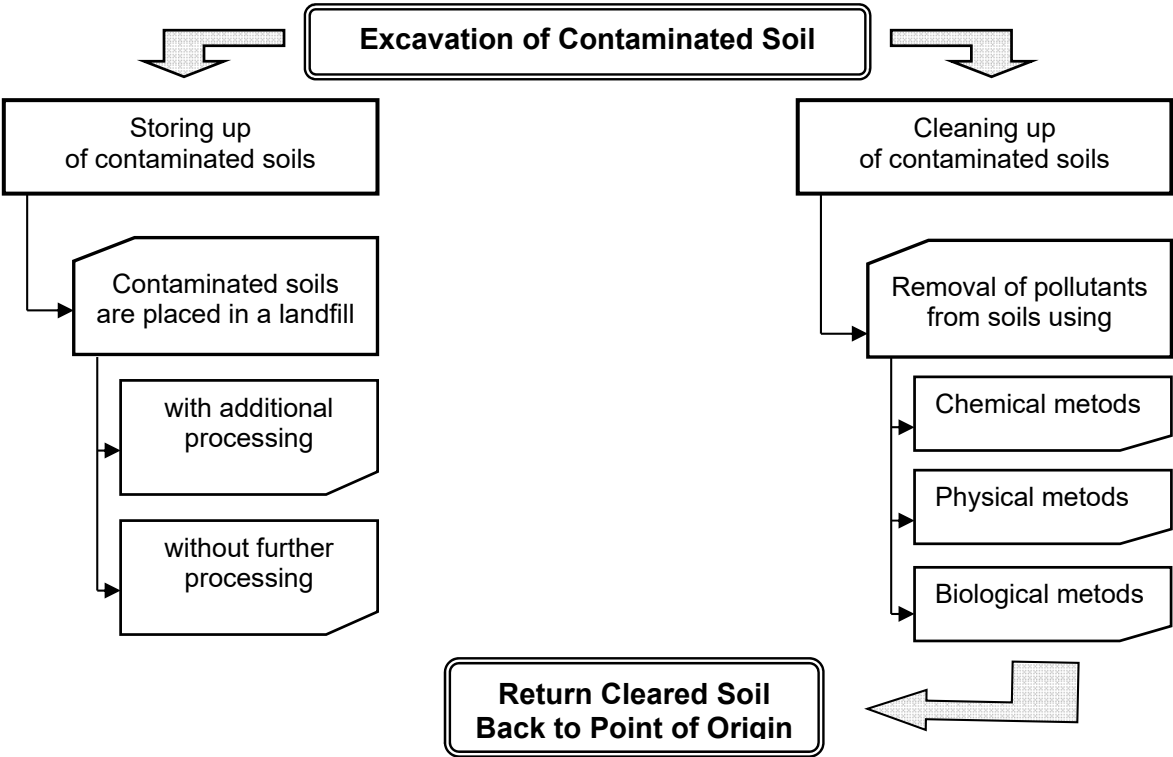

Fig. 1. Concept pattern “*ex situ* healthy soils contaminated by heavy metals and radionuclides”.

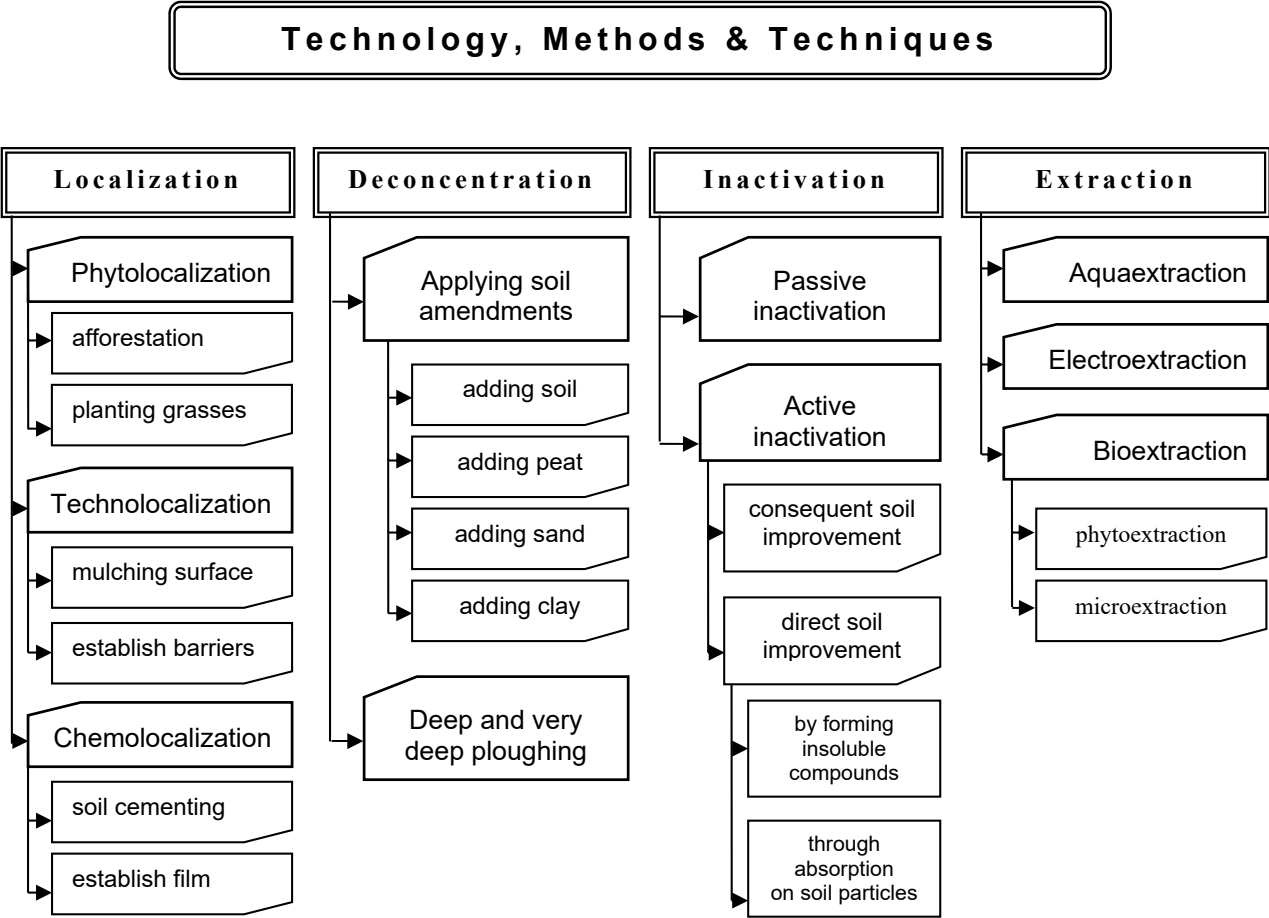

Fig. 2. Concept pattern “In situ healthy soils contaminated by heavy metals”.

Chemolocalization involves limiting the distribution of metals from contaminated territory, with the help of obstacles formed as a result of chemical reactions. Depending on the place of the reaction and the chemism of the formation of such barriers, chemolocalization is divided into: subsurface cementing and the creation of a protective film. The technology of subsurface cementing involves the introduction of special reagents into the soil, which determines the chemical bonding of pollutants and the formation of special granules. The technology for creating a protective film involves applying special substances to the surface of contaminated soil, which, as a result of chemical interaction with each other, as well as with soil components, form a stable coating. Such a coating, isolating the contaminated soil surface from the action of wind and precipitation, prevents the emission of pollutants as a result of erosion [30].

Deconcentration is a technology that involves mixing the contaminated soil horizon with uncontaminated soil layers and / or loose soil-like substrates. As a result, there is a decrease in the concentration of metals in soils. In practice, two methods of deconcentration of metals in soils are possible: 1) application of soil-like substrates, 2) deep plowing (Fig. 2).

Inactivation is a technology that involves the transfer of metals from the active (liquid phase of the soil) to inactive (solid phase of the soil). Inactivation of metals is divided into passive and active (Fig. 2).

The principle of passive inactivation of metals is to restore the natural fertility of the soil. The principle of active inactivation is the direct transition of metals to inactive forms due to: 1) the occurrence of certain pedogeochemical reactions, 2) the creation of special pedogeochemical conditions. In the first case, technologies of active direct inactivation of metals are implemented. The second implements technologies of active indirect inactivation of metals [12, 14, 32, 51].

It is promising to use: 1) clay content of a substance, 2) humic substances, 3) phosphate compounds, 4) calcareous materials, 5) industrial waste products, 6) specially synthesized substances for active direct inactivation of metals in soils. For active indirect inactivation of metals in soils, it is promising to use: 1) organic fertilizers (manure, peat, compost), 2) mineral fertilizers, 3) chemical reclamation reagents (lime, gypsum).

Extraction – those technologies that are aimed at the complete extraction of metals from the soil. The extraction of metals from the soil can be realized as: 1) aqua extraction, 2) electroextraction and 3) bioextraction (Fig. 2).

Aqua-extraction involves translocation of metals from contaminated soil layers beyond the soil profile using water and / or aqueous solutions of special reagents.

Electroextraction involves the extraction of metals from the soil due to the action of chemical reactions that obey electrokinetic's laws. Fundamentally, this technology is based on the directional movement of metals in the presence of an external electric field.

Bioextraction is based on the ability of living organisms in the process of their life to extract from the

soil and accumulate metals in their bodies. As a result, there is a process of translocation of anthropogenic metals in the direction of “soil – living organisms”. Bioextraction should be divided into: phytoextraction, zooextraction, microextraction and fungiextraction. However, in practice, bioextraction is represented mainly by two technologies: phytoextraction and microextraction.

Phytoextraction is based on the natural ability of plants to absorb from the environment and accumulate metals in their tissues. As a result, directional translocation of metals from the soil to the aboveground phytomass occurs, which eventually collects and moves away from the territory. The result – the concentration of metals in the soil is gradually reduced to the required level. Studies of the last 20-25 years have shown that about 400 plant species from 45 families can be considered as metal hyperaccumulators [29, 30, 42, 43].

An innovative way to increase the efficiency of phytoextraction of metals from soils is the use of chemicals that significantly increase the flow of metals in the Soil – Plants system. Such substances are called “activators” or “effectors” for the phytoextraction of metals from soils [4, 10, 30].

In the global perspective, it is possible to use phytoextractors enriched with biomass metals as phytogenic raw materials for the enrichment industry. Therefore, in the future, a wide-scale application of phyto-ore and phyto-mining technologies is possible.

Microextraction is a technology that is based on the use of the natural abilities of microorganisms as metal acceptors.

In this regard, it is assumed that there will be a targeted extraction of pollutants from the soil with their subsequent accumulation in microorganisms.

Microorganisms are able to extract metals from the soil as a result of reactions: adsorption, precipitation and oxidation; changes in the valence of metals, extracellular chemical deposition, volatilization; oxidation, immobilization and binding; binding, changes in the valence of metals, volatilization, extracellular chemical deposition and symbiosis with plants [6, 13, 43, 47, 51].

3.3.2 Environmental healthy of radionuclides' contaminated soil

The radiation background following the Chernobyl nuclear power plant (ChNPP) accident in April 1986 was determined by 21 radionuclides. Most of them fell out with fine carbon particles (with adsorbed metal atoms condensation forms), as well as in the form of fuel particles. The greatest danger to living organisms was represented by a biologically active radionuclides group: ^{131}I ; ^{90}Sr ; ^{137}Cs ; $^{238,239}\text{Pu}$; ^{141}Ce ; ^{144}Pr ; $^{103,106}\text{Ru}$; ^{95}Zr ; ^{95}Nb . Heterogeneous in their dosimetric characteristics, these radionuclides have one thing in common: most of them are counterparts, analogues of chemical elements that perform important biological functions in living organisms and plants [16, 17, 22].

Radioisotopes with a long half-life are especially dangerous. This group includes such surface pollutants

as ^{90}Sr , ^{137}Cs , ^{241}Am and all plutonium isotopes. ^{137}Cs and ^{90}Sr pose the greatest danger to humans, animals and plants. They are easily integrated into trophic chains and are sources of internal and external irradiation of organisms. It is known that ^{90}Sr is an analogue of Ca and ^{137}Cs is K. They are well soluble in water, easily absorbed by soil and are biologically mobile in agricultural chains, and have a long half-life ($T_{1/2}(^{137}\text{Cs}) = 30,7$ years; $T_{1/2}(^{90}\text{Sr}) = 28,1$ years) [2, 7, 9].

^{137}Cs is one of the major dose-forming radionuclides among fission products. An important feature of this isotope is the ability, along with exchange binding, to solid phase soil sorption (fixation), in particular, entry into interpacket spaces and fixation of Cs^+ ions by a crystal lattice of some secondary clay minerals. Firmly fixed Cs^+ ions are less likely to be converted into soil solution and therefore become less accessible to most crops. Unlike ^{137}Cs , the main mechanism of absorption of ^{90}Sr by the solid phase of soil is ion exchange. The sorption of this radionuclide by the solid phase of the main soil types depends on the presence of macroconcentrations of other cations and anions in the soil solution [11, 15, 22, 36].

According to N. V. Timofeev-Resovsky [39, 40], the availability of radionuclides for plants depends primarily on soil properties and their behavior in soil (soil chemistry of radionuclides). The absorption of radionuclides by soil is determined by their distribution between the solid phase of the soil and the soil solution and is carried out at the expense of the processes of sorption – desorption, precipitation-dissolution of difficult-soluble compounds and coagulation – peptization of colloidal particles. The formation and dissolution of precipitation depends on the ionic composition, pH, Eh of the soil solution, and the presence of organic and inorganic acids. Adsorption of radionuclides from soil solution by solid phase of soil is closely related to the properties of mineral, organic and organomineral colloids [33, 35].

The behavior of cesium isotopes (^{134}Cs and ^{137}Cs) is determined by the fact that they are radioisotopes of an alkaline element having an oxidation degree of only +1 in any component of the natural environment. One of the most important features of these isotopes is the ability to invariably adsorb (fix) the solid phase of the soil, leading to a decrease in soil motility and a decrease in plant accumulation. The combination of soil-chemical (crystal-chemical) reactions leading to a decrease in the mobility of radionuclides in the soil due to their entry into the interpackage spaces of secondary minerals is commonly called “aging” [31, 37, 41].

The absorption and strength of ^{137}Cs by soil are significantly influenced by the content of K^+ ions and the presence of other competing cations in the soil solution. Thus, substitution in the soil-absorbing soil complex of all exchange cations by K^+ or Ca^{2+} ions markedly increases the sorption of Cs^+ ions. By reducing the influence on the sorption of the radionuclide by the solid phase of the soil, the cations competing in the soil solution can be arranged in the following order: $\text{Cs}^+ > \text{Rb}^+ > \text{NH}_4^+ > \text{K}^+ > \text{Na}^+ > \text{Ca}^{2+} > \text{Mg}^{2+} > \text{Sr}^{2+}$.

Unlike ^{137}Cs , the main and only mechanism for the absorption of ^{90}Sr is ion exchange. The behavior of this isotope in soil is determined by the behavior of an isotope carrier (stable Sr) and a chemical analogue (stable Ca).

Absorption of this radionuclide by the soil solid phase is closely related to the concentration in the soil solution of other cations. The content of exchangeable Ca in the soil has a major influence on the uptake of ^{90}Sr into agricultural plants, and the cations on their competitive ability to influence the absorption of a given radionuclide can be arranged in the following order: $\text{Al}^{3+} > \text{Fe}^{3+} > \text{Ba}^{2+} > \text{Ca}^{2+} = \text{Sr}^{2+} > \text{Mg}^{2+} > \text{Cs}^+ = \text{K}^+ > \text{NH}_4^+ > \text{Na}^+$.

When large quantities of Ca^{2+} cations are introduced into the soil, as a rule, there is a sharp decrease in the $^{90}\text{Sr} / \text{Ca}$ ratio in the soil solution, which leads to a sharp decrease in the flow of the first to the plants.

As noted by several authors, the concentration in soil solution of anions PO_4^{3-} , SO_4^{2-} , CO_3^{2-} also influences the behavior of radionuclides in the system “soil-plant”. Thus, the availability of ^{90}Sr decreases due to the increase in soil solution concentration of PO_4^{3-} anions as a result of the formation of $\text{Sr}_3(\text{PO}_4)_2$ and SrHPO_4 compounds inaccessible to plants.

Many domestic and foreign researchers believe that the main role in the behavior of radionuclides is played by the agrochemical properties of soils. At present, about ten basic parameters are distinguished from all the physicochemical characteristics of soils, which affect the mobility and accessibility of ^{137}Cs and ^{90}Sr , which in increasing importance can be placed in the following order: > organic matter content > exchange contents K, Ca, Mg > cation exchange capacity > pH.

According to several scientists, the main mechanism of radionuclide movement along the soil profile is the process of diffusion from the zone of high concentration to the zone with lower concentration, transfer in a stream with a fine fraction of soil and transfer in the composition of soluble organic compounds (fulvates and humates) [16, 21, 28, 38].

A significant difference in the mobility of ^{137}Cs and ^{90}Sr in the soil should be noted. As ^{137}Cs can be fixed by mineral components of the soil, their movement along the soil profile is characterized by transfer with fine particles of the soil in a fixed state, whereas 10-40% ^{90}Sr is bound by the humates of the soil absorbing complex (humic, humatomyelin, and especially fusional forms). Bonding with soil organic matter explains the greater mobility in soils of ^{90}Sr compared to ^{137}Cs . A confirmation of the faster ^{90}Sr pre-vision is the increase in the proportion of its exchange forms as it sinks, which is not characteristic of ^{137}Cs . For most radionuclides, increasing the humus content in the soil provides a steady decrease in the size of their transition to the plant. According to G. A. Sokolik with colleagues the availability of ^{90}Sr for plants in ionic form is 2-4 times higher than from organomineral complexes. The authors found that the ^{137}Cs transition from humates was 1.3-1.5 and ^{90}Sr 2-2.5 times lower than from fulvates.

According to some scientists [14, 33, 35], the increase of humus content in sod-podzolic sandy

loam soils from the minimum (1,0-1,5%) to the optimum (2,0-3,0%) was accompanied by a decrease of 1.5 times the ^{90}Sr and 2-5 times ^{137}Cs in the crop of perennial cereals.

The power and ash content of the peat layer are important factors influencing the intake of radionuclides into the crop of perennial grasses on peat-bog soils. It has been established that the cultivation of peat soils leads to an increase in the mineralization of peat mass (an increase in the ash content) and to a decrease in the radionuclide input into the grass.

In the period from 1986 to 1992, a stable positive balance of calcium, potassium and organic matter in soils was maintained in the majority of Belarusian farms located in the contaminated radionuclide zone. This, along with other measures, contributed to a significant reduction in the transition of radionuclides to products.

Since 1993, due to economic difficulties, the volume of soil fertility maintenance has declined sharply. This raises the fear of a decline in the rate of improvement of crop production, and in some places exceeds the permissible levels of radionuclide content in forage crops. In some cases, maintaining a higher humus content in the soil (3,1-3,5%) may be justified for the radioactive contamination zone in order to further reduce the radionuclide intake in the presence of cheap sources of organic matter (straw, green fertilizers) [31].

The particle size distribution of soils largely determines their absorption capacity and the sorption processes of radionuclides occurring therein. The sorption capacity of soils is directly proportional to the degree of dispersion of the soil particles. The soils of heavy granulometric composition have a larger number of fine fractions than light soils.

K. K. Gedroyts [14] pointed out that the silt fraction of the soil plays a major role in the exchange capacity of soils. The role of larger mechanical soil elements in the physicochemical absorption is small. The soil fraction larger than 0,001 mm has an absorption capacity from 0,12 to 13,4 mg-eq. per 100 g soil. Particle fraction less than 0,001 mm has an absorption capacity from 20,6 to 107,4 mg-eq. per 100 g soil.

Soils containing a large number of fine particles (smaller than 0,001 mm in size) are characterized by a high absorption capacity. As the particle size decreases, the content of silicon oxide decreases, the amount of one and a half oxides of iron and aluminum increases, and the content of humus and exchange cations of calcium, magnesium and potassium increases (the latter is especially important for radionuclide sorption processes). The smallest dust and silty particles have the highest content of organic matter.

With the reduction of the size of the soil fractions, the strength of their ^{90}Sr and ^{137}Cs strength increases. For example, in the fine sand fraction of sod-podzolic soil and chernozem, 37-45% of the absorbed amount of cesium remains not displaced after three treatments by ammonium chloride. This indicates that the mineral part of the soil particles is of great importance in the sorption of ^{137}Cs .

Dusty fractions have an even greater ability to fix cesium radioactive isotope than sandy ones. Thus, in the

silt fraction of soils, the highest amount of ^{137}Cs remains, which are not displaced into the ammonium chloride solution after repeated treatment. From a practical point of view, it is interesting to monitor the distribution of radionuclides by the fractions of contaminated soils. The bulk of ^{90}Sr is concentrated in silty and clayey soil fractions of different types. The clay fraction (less than 0,01 mm) accumulates from 50 to 85% ^{90}Sr of the total soil content. It should be borne in mind that the proportion of different fractions in the particle size distribution of soils is not the same. In addition, differences in the properties of granulometric elements of varying degrees of dispersion are explained by the features of the mineralogical composition. In the clayey and colloidal fractions of soils secondary minerals – groups of montmorillonites, vermiculite – predominate. All of them (unlike primary minerals) are characterized by high absorption capacity, including for radionuclides.

According to some researchers, the sorption of radionuclides by soil depends to a large extent on its mineralogical composition. Thus, 98-99% of the ^{137}Cs concentration in the soil is sorbed by minerals of the montmorillonite group, mica and hydromica. By the ability to absorb and firmly retain ^{137}Cs minerals can be arranged in descending order: ascanite, hydroflogopite, phlogopite gumbrin, vermiculite, bentonite, kaolinite, vivianite, muscovite.

Secondary clay minerals can also be sorbed up to 99% of ^{90}Sr content in soil. For example, from soil solutions montmorillonite group minerals were absorbed from 92,1 % to 99,9 % of ^{90}Sr content in soil. The kaolinite group minerals were absorbed from 40 % to 68 % of ^{90}Sr content in soil. The mica minerals were absorbed from 71 % to 87 % of ^{90}Sr content in soil. The minerals of the calcite, feldspar and quartz groups were absorbed 10 to 50% of ^{90}Sr content in soil. Preferably, this radionuclide is sorbed by such minerals as ascanite, bentonite, vermiculite, phlogopite igumbrite. To a much lesser extent, it is sorbed by hydro muscovite and hydrogetite.

In our opinion [27], differences in the completeness of sorption of radionuclides from the soil by different minerals are due, first of all, to the different structure of their crystal lattice. Thus, the minerals of the montmorillonite group (ascanite, gumbrine), as well as the minerals of the mica and hydromica group, due to the structure of the crystalline lattice, have intramolecular absorption (cations entering the crystalline lattice). Therefore, they more fully absorb the micro-amounts of radionuclides from the soil. In addition, these minerals more firmly fix them in the absorbed state compared to the minerals of other groups (kaolinite group). These minerals are characterized by extracellular absorption (absorption of cations on the surface of crystalline lattice layers).

Therefore, the stronger anchoring of ^{137}Cs with soils compared to ^{90}Sr is due, first of all, to the strong sorption of this radionuclide by the mineral part, especially by the highly dispersed fractions containing the minerals of the montmorillonite group and the group of hydro-mica.

The ^{137}Cs -free carrier can be absorbed by the soil by sorption of the element on the surface of the three-layer

minerals. However, it cannot be substituted for hydrogen, sodium, calcium, magnesium or barium ions. Because, these ions not a component of the soil crystal lattice.

^{137}Cs micro-quantities in soil can only be partially replaced by potassium, ammonium and stable cesium. It was also found that the decrease in the availability of ^{137}Cs under the influence of the flagopite and the hydroflagopite is due not only to its strong fixation in the crystal lattice, but also to the content of mobile potassium in this mica.

It should be noted that among the lands contaminated by radionuclides of the Republic of Belarus and Ukraine, more than half are soils of light granulometric composition. Therefore, these soils are characterized by low absorption capacity, low content of humus and secondary clay minerals, increased hydromorphicity and high rates of transition of radioactive substances to agricultural crops. These factors make it difficult to obtain "pure" crop and livestock products (containing radionuclides within the limits of radiation safety).

According to the degree of permeability of radionuclides on the soil profile of different granulometric composition, the following series can be constructed as it decreases: sands, sandy loam, and loam. According to the researchers, the determining factor for the radionuclides from soil to plants is the properties of the soil absorbing complex. The strength of sorption of radionuclides in soil is higher; the greater is its cation exchange capacity and the sum of exchange bases. Strong sorption of ^{137}Cs and high availability of ^{90}Sr at root admission were noted. Some scientists play a significant role in the absorption of radionuclides (^{134}Cs , ^{137}Cs , ^{85}Sr , ^{90}Sr) by soil parameters such as temperature, pH, and the ratio of liquid and solid phases of soil solution.

It was found that the concentration of ^{90}Sr in meadow plants with decreasing pH and exchange calcium in alluvial soil decreased. Increasing the fraction of silty fraction in the humus-accumulative horizon above the specified soil type decreased the concentration of both ^{137}Cs and ^{90}Sr .

According to many researchers [33, 35], pH is the leading soil factor that determines the mobility and availability of radionuclides. Thus, humic and other low molecular weight acids limit the mobility of radioactive elements. Therefore, the absorption strength of radionuclides by the soil absorption complex, on the contrary, is weakened. The reason due to the formation of negatively charged complex compounds of iron and aluminum with fulvic or oxalic acids. It has been established that soil acidity exerts both direct and indirect acidity on the entry of radionuclides into prairie grasses (changes the cation exchange capacity). However, depending on the physicochemical properties of soils and species differences of prairie plants, the conversion rates of radionuclides into grasses can vary widely (from 0,03 to 79,91 times). Interspecies differences in ^{90}Sr accumulation depending on these properties can reach 30 or more times [30-36].

Thus, the magnitudes of translocation of radionuclides from contaminated soils into plants depend

on: 1) the physicochemical properties of soils, 2) the forms of radionuclides in the soil, 3) the basic agrochemical characteristics of soils: a) mineralogical and granulometric composition, b) the content of organic matter and humus, c) soil acidity, d) indicators of the cationic composition of soil solution and soil-absorbing complex (absorption capacity of the degree of saturation of the bases).

In order environmental health of radionuclides' contaminated soil (mainly by ^{137}Cs and ^{90}Sr), it is important to use the following technologies: 1) localization, 2) deconcentration and 3) inactivation (Fig. 2). At the same time, the techniques of inactivation of these radionuclides should be recognized as a priority technology. For this, information on the behavior and distribution of radionuclides in the soil is very relevant

4 Conclusions

In general, modern environmental technologies of healthy soils contaminated by heavy metals and radionuclides are characterized by a considerable variety of action strategies (*in-situ*, *ex-situ*) and practical techniques / methods / ways. In extreme cases (very high and extremely dangerous concentrations of these pollutants in soils) it is advisable to use *ex-situ* technologies for healthy soils. In most cases, *in-situ* technology should be used for healthy soils. Among these technologies, from an environmental point of view, priorities are localization, deconcentration and inactivation. From an ecological point of view, priorities are extraction of pollutants from the soil. The effectiveness of healthy soils contaminated by heavy metals and radionuclides is conditioned by the skillful application of several technologies.

Abstract. Recent advances in preparation and use of gallium and indium nanoparticles and nanocomposites are briefly presented. The following applications of the obtained materials are outlined: (i) Preparation of sensors for measuring in air of gaseous pollutants (carbon monoxide, nitrogen dioxide, hydrogen sulfide, ammonia, ozone, hydrogen), vapours of volatile organic compounds (methanol, ethanol, butanol, acetone, liquefied petroleum gas), and humidity, including the basics of the sensing mechanism; (ii) removal of water pollutants by photocatalysis and/or adsorption. Finally, conclusions are drawn about the potential of gallium and indium nanoparticles and nanocomposites and the further studies needed to achieve the implementation of these materials in the real life.

1 Introduction

Gallium (Ga) and indium (In) are minor metals applied in advanced technologies needed for the society sustainable development and for our everyday comfortable life. Gallium arsenide is mainly used to manufacture integrated circuits (ICs) and optoelectronic devices. Gallium nitride (GaN) is used to produce optoelectronic devices. For example, Ga consumption in ICs was 68% of the total Ga used in 2018 in the USA, optoelectronic devices accounted for 30%, the left to 100 % was used in research and development, medicine, etc. [1]. In Europe the electric and electronic equipment (EEE) sector is the main user of Ga - 95 % of the element usage [2].

Indium is used mainly as indium tin oxide (ITO). ITO thin-film coatings are employed mainly for electrical conductive purposes in different flat-panel displays. Other In uses are alloys and solders, compounds, semiconductors and electrical components, and research [3]. In the European Union the EEE sector is the major user of In (81 %) [2]. Application of In and Ga in the advanced renewable energy technologies (solar cells, electrodes for hydrogen (H₂) production via water splitting, etc.) and the environment protection activities (pollutants sensing, monitoring and removal) is gaining increased interest recently.

Expected problems with Ga and In supply led to these metals classification in 2017 as critical for Europe materials [4] and as critical for the USA - in 2018 [5]. Materials with high supply risk and above the average economic importance compared to the other raw materials are classified as critical. Increasing the comprehensive use of those metals can be pointed out as one of the measures aimed at mitigation of their expected shortage. Application of nanosized particles (NPs) and nanomaterials, with significant surface area at low mass,

may be a step in this direction. In addition, nanomaterials' characteristics are size-dependant and their properties can be tuned by changing the particles size and morphology. The exceptional properties of NPs and nanomaterials attracted the attention of scientists and a tremendous amount of work has been carried out in the area of synthesis, characterization and use of those materials in industry, medicine and the environment protection.

Work on the synthesis and use of Ga and In based nanomaterials has been increasing in the recent years. Present paper is devoted to the latest studies in this area. Applications (still niche) of Ga and In NPs and nanomaterials for green energy production and the environment protection are reviewed. An attempt is made to present examples covering the diversity of these applications.

2 Sensors for air pollution

Carbon monoxide (CO) results in elevated concentrations in the environment mainly from anthropogenic activity (industry, transport). Inhaling CO can cause headache, dizziness, fatigue, to affect hearth and damage the nervous system. Higher exposure to CO can cause sleepiness, hallucinations, convulsions, loss of consciousness while extremely high exposure leads to coma and death. The Occupational Safety and Health Administration Agency (OSHA) of the USA limits the long-term workplace exposure levels, i.e. the permissible exposure limit (PEL) for human, to 50 ppm. The USA National Institute for Occupational Safety and Health (NIOSH) places airborne exposure limit (REL) at 35 ppm which should not be exceeded at any time and 200 ppm not to be exceeded during any 15-minute period [6].

Nitrogen dioxide (NO₂) is produced by automotive vehicles and industry. It is one of the main factors of the

* Corresponding author: marichim@mgu.bg

formation of acid rain and the hole in the ozone layer. NO₂ possesses hazardous effects on human health. OSHA places the PEL at 5 ppm averaged over an 8-hour work shift, while the NIOSH's REL is 1 ppm averaged over 10 hour shift [6]. The World Health Organization reports that short-term exposure at concentrations exceeding 200 µg/m³ (106 ppb) NO₂ leads to significant negative health effects to humans [7]. That is why advance is needed in portable gas sensors which could detect NO₂ at ppb level.

Hydrogen sulfide (H₂S) causes nausea, dizziness and high exposure may cause a pulmonary edema. OSHA places the PEL at 20 ppm, while the NIOSH's REL is 10 ppm, which should not to be exceeded during any 10-minute period [6].

Ozone (O₃) can affect humans and animals even when it is in very low concentrations, causing irritation of respiratory system, headache and burning eyes. Continuing exposure to O₃ increases the risk of respiratory diseases, and at high concentrations O₃ has lethal effects. OSHA places the PEL at 0.1 ppm, and the NIOSH's REL is 0.1 ppm [6].

Ammonia (NH₃) is an irritant gas and its influence increases with its concentration. Higher exposures to NH₃ may cause pulmonary edema, while repeated exposure – asthma-like allergy and lung damage. Its increased concentrations in the atmosphere are due to anthropogenic sources, mainly use of NH₃ and its derivatives as agricultural fertilizers, but also - industry. OSHA places the PEL at 50 ppm, while the NIOSH's REL is 25 ppm, and 35 ppm have not to be exceeded during any 15-minute period [6].

Hydrogen (H₂) is flammable and explosive at the volume concentration higher than 4% in air [8]. It is expected to be extensively used in production of green and renewable energy in the future, so it is of high importance to develop a low-cost and effective H₂ sensor for practical use at working areas to provide early leakage and explosion warning.

Gas sensors have become a very important part of air quality monitoring, safe industry, etc. Development of commercial gas sensors based on semiconductor metal oxides (SMOs) has acquired a lot of attention, due to their low cost, and the simple use. Due to their ability to change the conductivity when they are contacting with the gas molecules, SMOs, among them indium oxide (In₂O₃) and gallium oxide (Ga₂O₃), are widely used in the electrical detection of polluting gases. The gas measurements are based on the change in the conductivity of the sensor due to the surface chemical reaction between the sensor's surface and the reducing or oxidizing measured gases. It is commonly acknowledged that the sensing of the n-type semiconductors is controlled by the resistance changing that is brought about by the adsorption and desorption of gas molecules on the surface of the sensor [9-14] as described below. When the sensor is exposed in air, the O₂ molecules from the air capture electrons from the semiconductor's conduction band (CB). Chemisorbed oxygen species (O₂⁻, O⁻, and O²⁻ – depending on the temperature) are generated on the surface of sensing material – equations (1-4). Electron-depleted near-surface region in the semiconductor is formed with the resulting electrical resistance of the sensor, denoted as R_a. When

oxidative gas, like NO₂, is introduced into the air, it captures electrons from the CB of the semiconductor, and it also combines with the adsorbed oxygen species, equations (5-6). This results in a decrease in electron concentration in the near-surface region, thereby the depletion layer and the sensing material resistance (denoted as R_g) increase. The ratio R_g/R_a is defined as the sensor's response. The sensors are recovered by placing in air, where species, like NO₂⁻, adsorbed on the sensor surface are desorbed - equation (7).

When the sensor is exposed to reducing gas (for example, CO, methanol or ethanol vapour, etc.) a redox reaction occurs between the adsorbed oxygen species and the molecules of the measured gas-equations (8-10).

Electrons are released and returned to the semiconductor's CB. This leads to the decrease of sensor's resistance. In this case the sensor's response is defined as the ratio R_a/R_g.

Two main directions are used to influence the interaction between the SMOs surface and target gas and thus to improve the gas sensing properties: (i) Application of nanomaterials, including decoration with metal NPs, since the performance of SMOs based sensors strongly depends on grain size, specific surface area and morphology of the sensing material. These properties can be tuned by carefully choosing the synthesis and processing conditions; (i) Doping – that improves the gas sensors characteristics by changing the energy-band structure and morphology, increasing the surface to volume ratio and as a result – creating more centers for gas interaction on the SMOs' surface. In addition, the dopant can act as catalyst that promotes the adsorption and surface reactions and hence improves the sensor performance by increasing the sensor response, reducing response and recovery time, reducing the operating temperature, and increasing selectivity.

2.1 Gallium NPs based sensors

Zinc oxide (ZnO) is one of the earliest and most often used gas-sensing materials. The similarities between ZnO and GaN gave raise to the interest in studying the gas sensing properties of GaN nanostructures. A hybrid structure,

based on GaN, namely Au@rGO/GaN nanorods (NRs), has been developed [15]. The Au@rGO/GaN NRs showed good response to 20 ppm CO that was attributed to interband transition in UV light and the localized surface plasmonic resonance in visible region. According to the authors [15], the Schottky junction (a specific property of reduced graphene oxide - rGO) contributed to the separation and transport of the photogenerated carriers. The Au NPs introduced electronic and chemical changes in the hybrid structure for improving photodetector's response towards CO.

Gallium doped ZnO (GZO) nanocrystalline films have been synthesized by radio frequency magnetron sputtering and their gas sensing properties with respect to H₂S were investigated [16]. Doping lead to enhanced sensing characteristics of the fabricated gas sensors and increased stability with respect to oxidation. Studies confirmed that among the doped films, GZO containing 3 wt. % Ga exhibited the highest sensitivity for H₂S at an operating temperature of 300 °C. The enhanced sensitivity of GZO for H₂S is attributed to the combined effect of excess oxygen vacancies due to Ga³⁺ substitution and the large adsorption energy of Ga that favours chemisorption.

Sensors based on core-shell Pt@ZnO NPs doped with 1 and 2 mol % Ga have been prepared and utilized in acetone^a and NO₂ sensing [17]. It is found that detection limit to acetone and NO₂ of the 1 mol % Ga doped Pt@ZnO based sensor was 10 ppb and 20 ppb correspondingly.

Composite material Ga₂O₃/Al₂O₃ has been synthesized by a two-step method including hydrothermal and calcining processes [18]. It is shown that Ga₂O₃ nanorods were dispersed on the surface of mesoporous 2D Al₂O₃ nanosheets. The Ga₂O₃/Al₂O₃ composite showed relatively good NO_x (i.e. NO₂ + NO) gas sensing performance. Its response to 100 ppm NO_x at room temperature was 58.2%, being 6.5 times higher than that of pure Ga₂O₃ and remained unchanged for 30 days. The composite material showed ~6 times higher sensitivity to NO_x (100 ppm) compared to HN₃ (100 ppm), ~16 times higher sensitivity compared to CO (1000 ppm), and ~16 times higher sensitivity compared to ethanol (1000 ppm) at room temperature.

2.2 Indium NPs based sensors

Sensors based on In₂O₃ or applying In₂O₃ as doping or decorating materials in other SMOs have been extensively developed and studied recently – for both inorganic and organic gases. Below are presented some examples.

Detection of low CO concentrations at room temperature still poses some challenges. Use of nanomaterials and nanocomposites are among the often considered possible solutions to the problem. Sensing of CO (1–5 ppm) at room temperature by using Zn doped In₂O₃ nanowire (NW) transistors was shown [19]. The doped In₂O₃ NW sensor exhibited enhanced response compared to pure In₂O₃ NW. Relatively good selectivity

to CO gas was achieved at comparison with NO and NO₂ (6 and 2 times higher sensor's response correspondingly). The improved response of the prepared sensor at room temperature is assigned to the created defects and to the change in conductivity of the nanowire as a result of Zn-doping.

Two materials (In₄Sn₃O₁₂ NPs and In₄Sn₃O₁₂-TeO₂ composite NPs) have been synthesized by hydrothermal route and their gas-sensing properties toward CO were examined at different concentrations (5–100 ppm) of CO in the temperature range of 100–300 °C [9]. The In₄Sn₃O₁₂-TeO₂ composite NPs sensor showed better sensing performance with response of 10.21, the response and recovery time of 19.73 s and of 217.5 s correspondingly for 100 ppm CO at 200 °C. The improved properties of the sensor are attributed mainly to the enhanced modulation of the potential barrier formed at the In₄Sn₃O₁₂-TeO₂ interface, the stronger O₂ adsorption on the TeO₂ (a p-type semiconductor), and the creation of favoured adsorption sites. The In₄Sn₃O₁₂-TeO₂ based NPs sensor showed selectivity (2-3 times higher response) to CO (100 ppm) over NH₃ (100 ppm), HCHO (100 ppm) and H₂ (1000 ppm).

A gas sensor based on cobalt (Co)-doped In₂O₃ NPs / molybdenum disulfide (MoS₂) nanoflowers nanocomposite has been prepared and tested with respect to CO (1, 5, 10, 50, 100, 500, 1000, 1500, and 2000 ppm) at room temperature [20]. The Co-In₂O₃/MoS₂ sensor achieved high sensitivity, fast response/recovery speed (response/recovery times = 39 s / 81 s), excellent repeatability and longterm stability (over one month). The high-performance CO sensing was attributed to the Co²⁺ ion doping and heterojunctions created at interface between Co-In₂O₃ and MoS₂.

Zinc oxide is widely used as a basis for preparing gas sensors. However, for the majority of ZnO based gas sensors, the lowest detectable concentration of CO is usually several hundreds of ppm. These values are higher compared to OSHA PEL. In order to improve the sensitivity of ZnO gas sensors for CO monitoring, In-doped ZnO semiconductor NPs (IZO NPs) materials were prepared by a sol-gel technique [21]. The materials were used to fabricate sensors that showed enhanced sensitivity to CO (50 ppm at 300 °C), compared to sensor based on pure ZnO, especially the sensors containing 1 at. % and 2 at. % In.

SMOs are promising choices for hydrogen sensors. Flame spray pyrolysis was used to synthesize palladium oxide (PdO_x)-doped In₂O₃ NPs (5 - 20 nm) [22]. From thus obtained NPs sensing films were prepared by spin coating and tested for their ability to measure H₂ at temperatures ranging from 150 to 350 °C in dry air. The studies revealed that the H₂-sensing characteristics of In₂O₃ NPs were considerably improved by PdO_x doping, especially at the optimal Pd content of 0.50 wt. %. The sensing film showed a response of 3526 towards 10000 ppm H₂ at 250 °C (the optimal working temperature), at response time of 2 s and recovery time of 180 s. Moreover, PdO_x doped In₂O₃ sensing films possessed good stability

^a Here and further in the text where a comparison is made with volatile organic compounds their vapors are meant.

and high H₂ selectivity against different gases, such as H₂S, NO₂, C₂H₄O, C₂H₄, C₂H₅OH and C₂H₂. The sensing mechanism is described by interaction of H₂ molecules with the preadsorbed oxygen species – reactions (11 – 13):

The processes produce H₂O and release the trapped electrons back to In₂O₃ CB, thus decreasing the sensor's resistance. The improved gas-sensing behavior is assigned to the effect of the formed p-n heterojunction of PdO_x-In₂O₃ and the presence of PdO_x crystallites which catalyze the dissociation of the H₂ molecules adsorbed on the material's surface.

The number of studies on NO₂ sensor development is expanding recently. Sensors based on In₂O₃ NP_s are promising in the NO₂ determination.

Packed In₂O₃ nanospheres have been synthesized via one-step solvothermal method followed by annealing [23]. The NO₂ gas sensing properties of thus prepared nanospheres were studied. The sensor showed response of 217.5 to 500 ppb NO₂, good stability and repeatability at the optimum operating temperature of 120 °C, with a detection limit lower than 10 ppb.

Doping and decoration of In₂O₃ nanomaterials with different metals is considered as a useful route for decreasing the sensors' operational temperature and the measured concentration ranges.

NO₂ sensors able to be used in ppb range of the pollutant concentrations were fabricated on the basis of Ag NPs decorated on hierarchical In₂O₃ nanospheres (Ag / In₂O) [10]. Fast response and recovery times of 30 s and 27 s correspondingly and detection limit of 0.5 ppb of NO₂ were found by using the synthesized Ag / In₂O sensor. Maximum sensitivity of 58 and 25.5 were achieved for 10 ppb of NO₂ at 120 °C for Ag / In₂O₃ sensor and primary In₂O₃ sensor correspondingly. Approximately 2.4-fold increase of NO₂ responses of the Ag / In₂O₃ sensor is observed compared to the response of primary In₂O₃ nanospheres to the concentrations ranging from 1 to 50 ppb of NO₂. Very good selectivity towards NO₂ was found – responses to 50 ppb of NO₂ were 110.2 and 265.6, respectively for primary In₂O₃ sensor and Ag / In₂O₃ sensor, compared to responses in the range of 1.3 - 2.8 and 1.6 - 4.8, respectively to 50 ppm of each of C₂H₅OH, CH₃OH, C₆H₆, C₆H₅CH₃, HCHO and CH₃COCH₃. The great performance of the Ag / In₂O₃ sensor is assigned to the hierarchical architecture of In₂O₃ nanospheres, the spill-over effect of metal Ag and the catalytic activity of Ag.

Ordered zirconium (Zr)-doped In₂O₃ (having Zr content of 0.5 wt%) with the pore sizes around 3 nm and undoped In₂O₃ nanostructures were synthesized via nanocasting and tested for their NO₂ gas sensing properties in the concentration range of 20-1000 ppm and the temperature range of 50-140 °C [24]. The Zr-doped In₂O₃ based sensor showed response of 169 toward 1 ppm NO₂ at the operating temperature of 75 °C, 3 times higher

than that based on undoped In₂O₃. A detection limit of 20 ppb was achieved by the Zr-doped In₂O₃. At 75 °C the Zr-doped In₂O₃ sensor exhibited much higher response towards 500 ppb NO₂ against other gases (10 ppm H₂S, 10 ppm NH₃, 100 ppm ethanol, 100 ppm acetone, 1 ppm SO₂, 1 ppm Cl₂, 500 ppb O₃). The enhanced properties of the Zr-doped In₂O₃ based sensor are ascribed to the ability of Zr-doping to increase the amount of chemically adsorbed oxygen and limit crystallites' size. In addition, the increased electrons' concentration of Zr-doped In₂O₃ makes its resistance very low thus facilitating its employment in portable devices.

Li and co-authors [11] proposed NO₂ sensors based on highly ordered In₂O₃, prepared by nanocasting method using mesoporous silica as template and decorated with Au NPs. The optimal sensor, based on 0.5 wt. % Au-loaded In₂O₃, possessed a response of 472 (7.1 times higher than the response of pure In₂O₃ based sensor) and a detection limit of 10 ppb at operating temperature of 65 °C. The selectivity of the sensor towards various gases, such as NH₃ – 100 ppm, Cl₂ – 10 ppm, CH₄ – 10 ppm, H₂S – 1 ppm, CO – 10 ppm, SO₂ – 10 ppm, and O₃ – 500 ppb, was studied. The response to NO₂ was ~ 100 fold higher compared to the selectivity to other gases, except of O₃, where it was ~ 10 fold higher. The excellent sensing properties of the Au NPs decorated In₂O₃ based sensor were mainly attributed to the ordered mesoporous structure and the catalytic activity of Au.

Ag-doped hollow urchin-like In₂O₃ hierarchical nanostructures were developed by solvothermal route followed by thermal treatment. They have been tested for NO₂ detection in the concentration range of 0.05 – 1.5 ppm NO₂ and the operation temperature range of 50 – 150 °C [25]. Best results were obtained for the sensor with 1.0 mol % Ag - with response of 190 to the target gas (1 ppm NO₂) at operating temperature of 62 °C. The sensor response increased almost linearly with increasing the concentration of NO₂ from 50 to 1000 ppb. The sensors based on Ag-doped In₂O₃ hierarchical nanostructures showed relatively fast response time (~5 min) and recovery time (~8 min). The sensor based on 1.0 mol % Ag doped In₂O₃ showed higher response to 1 ppm NO₂ (over 200 fold) in the presence of various gases (SO₂, Cl₂, CH₄, CO, C₂H₄, each one – 10 ppm and C₂H₅OH - 100 ppm) at 62 °C. The enhanced NO₂ sensing performance of Ag-doped In₂O₃ is attributed to its hierarchical structure and the catalytic activity of Ag NPs.

A metal-organic frameworks-derived In₂O₃ hollow microtubes / molybdenum disulfide NPs (In₂O₃/MoS₂) nanocomposite film sensor has been prepared using a layer-by-layer self-assembly method and its sensitivity towards 0.1–100 ppm NO₂ was studied at temperature of 25 °C [26]. It is found that the In₂O₃/MoS₂ composite sensor exhibited a response value of 371.9 toward 100 ppm NO₂, which is higher than the response of individual In₂O₃ sensor (of ~ 110). The sensor possesses a good linearity in the range 0.1 – 100 ppm NO₂ and reversibility. The response value of the In₂O₃/MoS₂ film sensor to 10 ppm NO₂ is much higher than towards the same concentrations of CH₂O, NH₃, C₂H₅OH, (CH₃)₂CO, C₆H₆, and H₂S, indicating high selectivity towards NO₂. The In₂O₃/MoS₂ nanocomposite-based sensor showed good

repeatability and stability upon exposure to 5, 10 and 100 ppm NO₂. The enhanced NO₂-sensing properties were assigned to the synergistic effects of In₂O₃ hollow microtubes and MoS₂ NPs.

Recently, improving the sensors characteristics by irradiation with UV light has been proposed. Walnut-like In₂O₃ nanostructures have been directly grown on the interdigitated electrode substrate by using a hydrothermal approach, followed by a thermal treatment [13]. The synthesized walnut-like In₂O₃ nanostructures have been used to fabricate a photoelectric gas sensor that was studied in the range of 0.1–50 ppm NO₂. A linear dependence of sensitivity on the NO₂ concentration was observed and the sensor showed sensitivity of 219 towards 50 ppm NO₂ when subjected to irradiation (1.2 mW/cm²) of UV light ($\lambda=365$ nm). The sensor possessed response of ~ 32 to 5 ppm NO₂ in the presence of other gases (50 ppm SO₂, 100 ppm CH₄, and 100 ppm CO) at room temperature. The sensitivity to the other gases was < 5 showing selectivity toward NO₂. The high performance of the walnut-like In₂O₃ was assigned to its high specific surface area, the enhanced interface force between the gas sensor substrate and the active material and effective participation of the photo-generated electrons.

Ozone has to be monitored in industrial applications (requiring high O₃ concentrations) and for the human and the environment protection, where low concentrations have to be measured. However, the majority of the commercial sensors are properly working only in one of the concentration ranges – low (ppb) or high (ppm). Indium oxide NPs can be used to solve the problem. A cheap portable photostimulated ozone sensor, based on In₂O₃ NPs, has been developed that was able to measure O₃ in the concentration range over four orders of magnitude at room temperature by changing the diameter of the In₂O₃ NPs [27]. It is based on the findings that the 7-nm In₂O₃ NPs can detect O₃ concentration between 10 ppb and 10 ppm, while the 12-nm NPs are suitable for O₃ detection between 10 and 200 ppm. By combining the two types of NPs, O₃ in the concentration range of 10 ppb – 200 ppm can be measured. The sensors' response to 12 ppb O₃ remained stable even in the presence of 1200 ppb CO, 100 ppm CO₂, or 100 ppb NO₂. However, increasing the NO₂ concentration up to 200 ppb lead to slightly higher response than that to pure 12 ppb O₃, while the response to 40 ppb O₃ was unchanged. The sensing signal was reproducible and hysteresis was not observed in measurements conducted for 35 hours. A small influence of the low humidity on the sensor response was observed. Sensor signals were found to be reproducible in a high-humidity gas environment and thus they can be accounted for. By sealing the sensor chamber with a porous hydrophobic membrane, which prevented the passage of liquid water, submerged measurements were carried out [28].

An organized monitoring of NH₃ concentrations is essential for decreasing the hazard for human health and plants. Regardless of this, the measurement of atmospheric NH₃ in urban areas has been usually unconsidered, since its average concentrations are generally low (in the 20–30 ppb range). A low-cost sensor

based on a mixture of single-walled carbon nanotubes (SWCNT) bundle layers with indium-tin oxide (ITO) NPs was prepared on plastic substrate [29]. The sensor exhibited high sensitivity to NH₃ (detection limit of 13 ppb) when used at room temperature. It displayed short recovery time and high selectivity in the presence of acetone and ethanol. The functionalized SWCNT exhibit a resistivity decrease when are exposed to water concentrations representative for ambient air (in the ppm range), revealing the possibility to differentiate the impact of interfering water vapour signal in the NH₃ measurement.

Methanol (CH₃OH) vapour causes headache, irritation of the eyes and mucous membranes. The repeated exposure to CH₃OH vapour may lead to metabolic acidosis, serious visual impairment, difficult to breathe. The OSHA PEL is 200 ppm, while the NIOSH REL is 200 ppm, and 250 ppm have not to be exceeded during any 15-minute period [6].

Pure ethanol (C₂H₅OH) irritates the skin and eyes. OSHA placed the PEL at 1000 ppm and the NIOSH's REL is also 1000 ppm [6]. Recently some studies have paid attention to the health risks related to inhalation of C₂H₅OH vapour [30].

Acetone ((CH₃)₂CO) vapour is irritating; exposure to its high concentrations affects eyes, nose and throat. The acetone PEL is 1000 ppm, the REL is 250 ppm [6].

The liquefied petroleum gas (LPG) vapour, when present in high concentrations in the air, can cause suffocation with symptoms of headache, dizziness, weakness, nausea, vomiting. The LPG PEL is 1000 ppm averaged over an 8-hour work shift, while the REL is 1000 ppm averaged over 10 hour shift [6].

Exposure to n-butanol vapours can cause headache, dizziness, nausea, vomiting. OSHA's PEL is 100 ppm averaged over an 8-hour work shift, while the REL placed by NIOSH is 50 ppm which should not be exceeded at any time [6].

In order to protect humans and the environment, sensors are needed that are able to detect the above-mentioned vapours.

Anand and co-authors synthesized pure and Ag-doped (1, 3 and 5 % Ag) In₂O₃ NPs by the co-precipitation method and studied their sensing properties towards CH₃OH, C₂H₅OH, (CH₃)₂CO and LPG at different operating temperatures [31]. Best results were obtained with 3% Ag-doped NPs whose maximum response (R_a/R_g) was ~30 towards C₂H₅OH at the operating temperature of 300 °C, ~15.5 towards (CH₃)₂CO at 350 °C, ~17 towards LPG at 400 °C and ~12 – towards CH₃OH at 300 °C – at the concentration of 50 ppm of each tested gas. The response time for In₂O₃ – 3% Ag sensor was between 6 and 32 s while for undoped In₂O₃ sensor – between 10 and 40 s, depending on the measured concentration. The improved sensing performance of 3% Ag-doped NPs based sensor is assigned to (i) the large number of oxygen vacancies leading to increased amount of O₂ adsorbed on the sensor surface as compared to pure In₂O₃ sensor, and (ii) the catalytic effect of Ag – Ag improves the sensor response by the formation of activated species of the chemisorbed analyte, which are

then spilled onto the surface of In_2O_3 . That results in fast reaction between the analyte molecule and oxygen.

Liu and co-authors further decreased the optimum measuring temperature and the concentration range (from 1 ppm to 50 ppm) by demonstrating $\text{C}_2\text{H}_5\text{OH}$ gas sensor based on indium oxide / molybdenum disulfide ($\text{In}_2\text{O}_3/\text{MoS}_2$) nanocomposite prepared via hydrothermal route [12]. The reported sensor response at 260 °C for $\text{In}_2\text{O}_3/\text{MoS}_2$ composite was ~36, while for pristine In_2O_3 it was ~14 at 280 °C. The responses of the two sensors show almost constant value to 50 ppm of $\text{C}_2\text{H}_5\text{OH}$ at 260 °C over 50 days, demonstrating the high stability of these sensors. The $\text{In}_2\text{O}_3/\text{MoS}_2$ sensor showed selectivity to $\text{C}_2\text{H}_5\text{OH}$ (150 ppm) in presence of C_6H_6 (250 ppm), $(\text{CH}_3)_2\text{CO}$ (350 ppm), NH_3 (450 ppm), and H_2O (5500 ppm). The improved characteristics of $\text{In}_2\text{O}_3/\text{MoS}_2$ nanocomposite sensor, compared to pristine In_2O_3 sensor are assigned to the large specific surface and good electrical properties of MoS_2 , as well as to the synergistic effect between In_2O_3 and MoS_2 . It is suggested that the MoS_2 nanosheets provide a platform for attaching In_2O_3 NPs, hampering their interparticle aggregation and providing more active sites for the adsorption of $\text{C}_2\text{H}_5\text{OH}$ molecules. It is concluded that the fabricated nanostructure favors molecular adsorption, gas diffusion and mass transport, thus improving the gas sensing performance.

Shruthi and co-authors prepared sensor based on $\text{Y}_2\text{O}_3\text{-In}_2\text{O}_3$ nanocomposites [14] and conducted gas sensing studies under room temperature. The $\text{Y}_2\text{O}_3\text{-In}_2\text{O}_3$ sensor responses of ~923 and 3.722 were found towards 200 ppm and 1 ppm CH_3OH correspondingly. The response and recovery times of $\text{Y}_2\text{O}_3\text{-In}_2\text{O}_3$ were 13 and 18 s respectively and the sensor showed stability over 30 days. The response and $\text{Y}_2\text{O}_3\text{-In}_2\text{O}_3$ gas sensor towards 200 ppm CH_3OH in presence of other gases (ethanol, n-butanol, acetyl acetone, ammonia, isopropanol, xylene, toluene, 2-methoxyethanol, acetone, and cyclohexane – each one 200 ppm) at room temperature was between 4.5 and 20 times higher compared to the response to the other gases thus proving the sensor's high selectivity. The enhanced properties of $\text{Y}_2\text{O}_3\text{-In}_2\text{O}_3$ sensor were explained by the formation of a n-n hetero junction between Y_2O_3 and In_2O_3 and the appearance of built-in potential.

Porous In_2O_3 NPs (20 - 50 nm) were prepared using a solvothermal method and studied as gas-sensing material for n-butanol – 50 ppm [32]. At 140 °C the sensor showed responses of 5.5, 10.3, 20.5, 32.4, 54.7, 97.3, and 241 for n-butanol concentrations of 5, 10, 15, 20, 30, 50, and 100 ppm, correspondingly. The sensor exposed to 50 ppm of other gases (ethanol, acetone, formaldehyde, benzene, xylene, methanol, ammonia, and n-butanol) exhibited good selectivity to n-butanol vapor. The good response of In_2O_3 NPs was assigned to their large specific surface area and porous structure that can provide more reactive sites and allow successful transfer of gases.

In some cases In_2O_3 is used as one of the components of nanocomposite applied as a sensing material. Humidity detection and measurement is one of the important parameters in the environment monitoring. Graphene oxide/Nafion/indium oxide ($\text{GO/Nafion/In}_2\text{O}_3$)

nanocomposite - based humidity sensor has been made-up and tested under a wide relative humidity range ($\text{RH} = 11\text{--}97\%$) at 25 °C [33]. The $\text{GO/Nafion/In}_2\text{O}_3$ film humidity sensor exhibited high sensitivity (especially at $\text{RH} > 80\%$), low hysteresis, good stability and repeatability. The sensor work is based on the increase in the capacitance with the increase in the RH, since the amount of water molecules physisorbed on the sensor surface increases as RH increases. The water molecules, possessing a dipole moment, can increase the capacitance of the nanocomposite.

Doping of other materials used for sensors with In compounds improves the performance of these materials. Crystalline ZnO nanorods were modified by In_2O_3 NPs using PVP as a morphology control agent via sol-gel and the hydrolysis method and the obtained material was used to prepare sensor for n-butanol vapor [34]. Tests showed that the $\text{In}_2\text{O}_3/\text{ZnO}$ sensor response was 104.3 towards the n-butanol concentration of 100 ppm at 370 °C. This was 3.5 and 5.3 times higher than the response of the pure ZnO and In_2O_3 sensor, correspondingly. The response and recovery times of the $\text{In}_2\text{O}_3/\text{ZnO}$ sensor were 6 s and 9 s at the gas concentration of 4 ppm. The response of the $\text{In}_2\text{O}_3/\text{ZnO}$ sensor containing 3.3 mol % of In was 6.1 at n-butanol concentration of 1 ppm, showing good detection. The $\text{In}_2\text{O}_3/\text{ZnO}$ sensor exhibited high selectivity to n-butanol (100 ppm) in the presence of ethanol, methanol, acetone, and ethyl acetate (each one 100 ppm). The enhanced sensing performance was ascribed to the 1D single crystalline nature of ZnO nanorods and the heterostructure established between In_2O_3 and ZnO nanorods.

3 Water pollutants removal

The scientific work has shown that the photocatalytic degradation of toxic organic pollutants is one of the most efficient methods for surface water purification. Ga and In NPs and nanocomposites are gaining their place in this area. The photochemical pollutant removal can result from direct or indirect interactions, or from the both types of reactions – Fig. 1. In the direct reaction pathway (Fig. 1a) the photogenerated holes (or electrons) directly oxidize (or reduce) pollutants that are adsorbed on the photocatalyst surface. In the indirect path (Fig. 1b) the excited electrons move to the surface of photocatalyst and react with O_2 to generate superoxide radical anions ($\bullet\text{O}_2^-$). At the same time, the corresponding holes move to the exterior of the photocatalyst and oxidize the water molecules or hydroxyl groups, present on its surface to produce hydroxyl radicals ($\bullet\text{OH}$). Thus formed reactive radical species are able to decompose and mineralize pollutants into CO_2 , H_2O and other inorganic species [35]. The light utilization efficiency, cost-performance ratio, and secondary toxicity are the major anxieties in the photocatalytic pollutants' removal.

3.1 Gallium NPs based materials

Titanium dioxide (TiO_2) NPs in anatase form are often used as photocatalysts. Anatase NPs doping with Ga by

applying sol-gel method is reported [36]. The NPs obtained (with size of around 15 nm) were used to study the photocatalytic degradation of organic dye solution (Rhodamine B) as a model pollutant under UV irradiation. Nearly 90% degradation efficiency was achieved within 3 hrs of UV irradiation when Ga-doped TiO_2 NPs were used, which is faster than the Rhodamine B degradation by undoped samples. The effect is ascribed to the fact that doping levels were created within the bandgap of TiO_2 . These levels act as trapping centers to suppress the recombination of photogenerated electrons and holes. In this way proper utilization of charge carriers is achieved for the generation of strong oxidizing radicals able to degrade the organic dye. Consequently the derived Ga doped TiO_2 NPs can be used for light-assisted oxidation of toxic organic molecules in the surface water for the environment protection.

Fig. 1. Schematic representation of electron-hole pairs photo-generation and their participation in pollutants removal: a) direct pollutants oxidation and/or reduction, b) indirect pollutants decomposition. Red dashed arrow – a possibility for recombination of photogenerated electrons and holes.

Fluoride ion (F^-) is mobile under natural conditions and can appear in elevated concentrations in water due to natural leaching of rocks. However, most often its high concentrations are due to anthropogenic activities such as metals' extraction, electroplating, etc. When F^- presents in drinking water in concentrations higher than the recommended, it can cause dental and skeletal fluorosis. With the aim to reduce the F^- concentration in water,

different methods have been developed, such as adsorption, ion exchange, precipitation, and membrane processes. Most of them are feasible when applied to point pollution sources. Adsorption can be applied also to polluted water discharged from diffusion pollution sources if the loaded adsorbent can be collected. Use of nanosorbents with magnetic properties is a big step in this direction. Improved selectivity and chemical reactivity are the other desired features of those adsorbents. As contribution in this area Fe_3O_4 NPs were synthesized by coprecipitation of Fe^{2+} and Fe^{3+} under alkaline conditions and their surface was then modified with 3-aminopropyltriethoxysilane (APTES) [37]. The Fe_3O_4 /APTES NPs were further modified by grafting Ga tetrakis (4-carboxyphenyl) porphyrin groups at their surface. The batch experiments using thus prepared NPs showed that they can be applied to remove F^- from aqueous solution. Extraction efficiency over 96% was achieved at an initial F^- concentration of 10 mg/L, pH 5.5 and contact time of 30 min. The Fe_3O_4 /APTES/Ga nanosorbent was successfully regenerated by using NaOH solution. The recovery of F^- ions from the adsorbent under optimum conditions was 98%. The fluoride removal efficiency by the Fe_3O_4 /APTES/Ga nanoadsorbent in 5 adsorption / regeneration cycles was 97.2%, 96.8%, 95.5%, 94.3%, and 87.0% correspondingly, showing the adsorbent stability.

3.2 Indium NPs based materials

In this application mainly indium sulfide (In_2S_3) materials are used, based on their photocatalytic properties. Due to its stability and low-toxicity In_2S_3 (with UV-Vis-NIR – solar-spectrum) can be used as promising photocatalyst and a sensitizer for other semiconductors with photocatalytic properties. The proper separation and transport of photo-induced charge carriers is one of the promising ways for improving the efficiency of In_2S_3 -based materials for pollutants' removal. Efforts have been made to decrease the recombination of photogenerated electron-hole pairs by morphology design, doping or producing heterostructured materials. The studies on nanosized In-based materials usage for water pollutants removal are devoted mainly to organic dyes, pharmaceuticals and microorganisms removal.

Gao and co-authors [38] have controlled the morphology of In_2S_3 NPs, thus adjusting the mass-transfer pathway for the photocatalytic removal of pollutants in the liquid-phase system. The tetragonal In_2S_3 NPs with size of 5–20 nm, synthesized by them, showed stable photo-catalytic removal of methyl orange (MO) over the entire solar light spectrum - under UV light (96.2% within 30 min), visible light (95.4% within 3 h) and near-infrared light (67.2% within 3 h). The broad light absorption region of the synthesized NPs is assigned to the presence of a defect band located above the VB of In_2S_3 .

Wu and co-authors [39] prepared a porous 3D microsphere-like In_2S_3 , stacked by 2D ultrathin nanosheets, which showed 3 times higher photo-degradation efficiency with respect to MO compared to 3D solid microsphere-like In_2S_3 . The better photocatalytic

activity was attributed to the relatively higher specific surface area and the presence of more reaction sites, which accelerated the surface separation of photo-induced charges and the inter-facial charge-carrier transfer.

Li and co-authors [40] prepared In_2S_3 - TiO_2 nanotube array composites by CV, potentiostatic and pulse electrodeposition. Their studies showed that the pulse prepared In_2S_3 - TiO_2 yielded the highest and stable photocurrent response, consequently showing an excellent photocatalytic activity in the degradation of p-nitrophenol. It was considered that the homogeneous, ultra-fine structure of In_2S_3 NPs lead to a high charge separation efficiency resulting in improved photocatalytic activity.

Self-organized TiO_2 nanotubes (NTs) array was decorated with In_2S_3 NPs to obtain ($\text{In}_2\text{S}_3/\text{TiO}_2$ NTs) hybrid that exhibited strong absorption in the visible light region and enhanced photocurrent density [41]. The $\text{In}_2\text{S}_3/\text{TiO}_2$ NTs showed higher photocatalytic activity when compared to that of bare TiO_2 NTs in the degradation of herbicide 2,4-dichlorophenoxyacetic acid (2,4-D) under simulated solar light. Approximately 100 % removal of the 2,4-D was achieved for 160-min irradiation by using the optimum $\text{In}_2\text{S}_3/\text{TiO}_2$ NTs composition. The removal efficiency was 95.1 % after 10 successive cycles. The photocatalyst has shown a good stability and easy recovery that gives grounds for its potential application for the photocatalytic removal of some organic pollutants from water.

Indium sulfide / zinc germanate ($\text{In}_2\text{S}_3/\text{Zn}_2\text{GeO}_4$) composites, with different In_2S_3 concentrations, were prepared via a co-precipitation hydrothermal method [42] and tested for their ability to decompose acetaminophen (APAP). The composite containing 30 mass % In_2S_3 showed the best activity for APAP degradation under visible light, with better performance compared to In_2S_3 , nitrogen-doped TiO_2 , TiO_2 powder (Degussa P25), and Zn_2GeO_4 . The studies revealed that holes and formed superoxide radicals were mainly involved in the photodegradation of APAP.

Hierarchical nanoflower superstructures consisting of In_2S_3 nanosheets grown on a Bi_2S_3 nanoflower backbone ($\text{Bi}_2\text{S}_3/\text{In}_2\text{S}_3$) were prepared by a solvothermal route, rest on different growth rates of the two sulphides [43]. The as-prepared $\text{Bi}_2\text{S}_3/\text{In}_2\text{S}_3$ material exhibited notable visible-light photocatalytic activity and stability in the degradation of 2,4-dichlorophenol. This is assigned to the presence of In_2S_3 nanosheets on the surface of the Bi_2S_3 nanoflowers which lead to increased visible-light response and enhanced photogenerated charge transport and separation steered by the heterojunction.

Hollow β - In_2S_3 NPs with high surface area have been synthesized by means of anion exchange process under a hydrothermal condition without any surfactant or sacrificial agent [44]. Adsorption capacity and photocatalytic activity of the newly prepared material were assessed, using methylene blue (MB) under dark and visible light irradiation. The big adsorption capacity (ca 158 mg/g in 60 min) for MB in the solution, realized in a fast process, was assigned to the high specific surface area (324.6 m^2/g) of the β - In_2S_3 NPs and to the electrostatic interaction between the negatively charged surface of β -

In_2S_3 and the MB. After the adsorption reaction, visible light photocatalytic reaction further decreased the concentration of the still existing MB. The removal efficiency for 100 mg/L of MB solution was 73.4% under dark for 60 min (indicating that adsorption plays an essential role for removing MB), and after further visible light irradiation for 180 min increased to 92.2%.

Tetragonal prismatic γ - In_2Se_3 NPs with the (110) facets were synthesized hydrothermally in the presence of ethylenediaminetetraacetic acid (EDTA) that plays a key role in the exposed facets regulation [45]. Studies on the photocatalytic decomposition of tetracycline (TC) by the newly synthesized material showed that the γ - In_2Se_3 NPs prepared with 0.04 M EDTA had the optimal activity ensuring degradation of TC in 120 min with an efficiency of 91.5%.

Gao and co-authors [46] investigated the visible light photocatalytic disinfection of water by using a photocatalyst prepared via joining non-woven carbon nanofibers (CNF) and In_2S_3 nanoflowers to construct three-dimensional hierarchical CNF- In_2S_3 nanostructures with large specific surface area and enhanced light absorption. Approximately 80 % of *Escherichia coli* cells were killed by CNF- In_2S_3 under visible light irradiation owing to the occurrence of oxidative stress. The good activity of the CNF- In_2S_3 photocatalyst was attributed to the enhanced light absorption, large surface area, and efficient charge separation that facilitate production of oxidizing species.

4 Conclusions

In conclusion, it can be said that Ga and In NPs and nanocomposites are materials showing potential for application in environmental protection. Materials based on Ga and In NPs are proposed for sensors for determining inorganic and organic polluting gases. In this application further work is needed in direction of increasing the response and selectivity in the low ranges of the measured concentrations, and of long-time stability of the prepared sensors (since most of the studies cover only 30 days).

In the water pollutants removal application most of the studies have been conducted with organic dye solutions. Consideration of other types of pollutants seems interesting. More data on the pollutants' decomposition products and investigations on the ways for collecting and separating from the water of the already used photocatalysts are needed.

The improvements in all above-mentioned directions can not be achieved without further research on the mechanisms of the proceeding reactions and phenomena and on the impacting factors.

Ending, we can say that Ga and In NPs and nanocomposites are promising materials but still much work is required for their implementation in the real life devices.

Utilization of mine water of Kryvbas as an imperative for sustainable development of Dnipropetrovsk region

Oleksandr Amosha, Hanna Shevtsova, and Ziya Memedlyayev*

Institute of Industrial Economics of the NAS of Ukraine, 2 M. Kapnist Str., Kyiv, 03057, Ukraine

Abstract. Sustainable development is a wide area of scientific discourse based on the interdisciplinary approach that integrates research in the natural, technical and social sciences. It is a multidimensional concept that reveals complex interactions between society, economy and environment. This work highlights problems of sustainable development of old industrial regions with the dominance of the mining industry. The latter creates a high human burden on the environment and leads to ecological and social problems. One of the most important tasks of ensuring the long-term environmental sustainability of the Dnipropetrovsk region in Ukraine is utilization of highly mineralized mine water of Kryvbas. From the standpoint of sustainable development, mine water should be considered as a hydro-mineral resource of many valuable components including bromine. In this work we justify the creation of bromine production from mine water of Kryvbas. Potential profitability of the production is largely based on innovative technical and technological solutions. We examine the market and many aspects of the pilot project, including its technological, investment and economic specifics. We highlight the relevance of this project and suggest a possibility for its implementation within the regional strategy framework.

1 Introduction

Sustainable development is a comprehensive interdisciplinary concept that covers different levels and areas of human life. It aims to bridge the gap between natural, technical and social sciences and to focus collective efforts on difficult challenges.

It is a multidimensional concept that investigates complex interactions between society, economy and environment. That is why most studies, particularly [1-3], examine three dimensions of sustainable development:

- 1) social solidarity (inclusive growth with equal opportunity for all people, poverty eradication, improving the well-being, gender equality, safety, social cohesion);
- 2) economic efficiency (economic growth, increased trade, employment, optimal use of limited resources, technological development, innovations, increased investment and productivity);
- 3) environmental responsibility (safeguarding the environment, keeping the equilibrium and integrity of ecosystems, waste management, control of climate change, biodiversity conservation).

The balanced development of these components is also important. N. Derlukiewicz [1] emphasizes that according to the sustainable development concept, future needs can be met depending on how well social, economic, and environmental objectives or needs are balanced.

S. Talukdar [4] conceptualizes sustainability in terms of environmental, physical, social and economic dimensions of sustainability. He also identifies two sustainability goals: continuity and aspiration.

D. Hanss & G. Bohm [5] discuss such dimensions of sustainability as environmental, social, developmental, temporal, and economic. According to the authors, development, new technologies, research and unsolved problems belong to developmental dimension of sustainability. We agree with this classification and use its elements in our case study. We think that this developmental dimension may also be called “innovative”.

E. Holden et al. [6] examines four primary dimensions: safeguarding long-term ecological sustainability, satisfying basic human needs, and promoting intragenerational and intergenerational equity. The authors also underline the distinction between narrow and broad sustainability. The narrow sustainability places great emphasis on long-term ecological sustainability. The broad sustainability also includes a wide range of political, social, economic and cultural issues.

Sustainable development is not only a scientific concept, but a political vision too. There are many regional, national, and global sustainability studies that have been successfully used in policymaking.

But eventually, we agree with I. Ilic-Krstic et al. [2] that the general concept of sustainability can have different forms depending on the framework being used. In the context of this study, the attributes of sustainable

* Corresponding author: shevtsova_hanna@nas.gov.ua

development are important for solving regional- and project-level problems.

The sustainable development approach is of particular significance to address the challenges in old industrial regions. Basic industries are dominant in these regions, because they were mostly formed and developed long ago.

Old industries are primarily based on extensive use of local raw materials, have outdated technologies, low productivity and accumulated environmental problems. Therefore, structural modernization is one of the key challenges in transformation of old industrial regions.

A number of researchers investigate problems of old industrial regions and a possibility of their neo-industrial modernization, see [7-11].

K. Birch et al. [7] studies diverse experiences among old European industrial regions and the role of national varieties of capitalism in shaping regional trajectories and the different mechanisms of regional adaptation. L. Coenen et al. [8] analyzes the potential, barriers and limitations for regional innovation policy to facilitate industrial renewal in old industrial regions.

The authors of [10] analyze how to ensure future sustainable development of old industrial coal-mining regions. The authors emphasize that there is no need for drastic changes, such as radical transformation in technologies, business organization patterns, or composition and quality of used resources (including labor). Instead, one may start with using technologies and business models that have a possibility to diversify the current economic activity. This possibility comes from similarity in the knowledge base and workers' qualification between different industries that are not connected both in the value chain and in the goods-dependent trade. An example of such diversification for the old coal-mining regions is a circular production that returns coal mining and enrichment waste back into production cycle by using innovative technologies.

Continuing research in this direction, we substantiate one of the possible project-level solutions as part of ensuring the long-term sustainability of the Dnipropetrovsk region in Ukraine.

2 The problem of Kryvbas mine water utilization

Dnipropetrovsk region is one of the most industrialized regions of Ukraine. According to State Statistics Service of Ukraine, it makes one fifth of Ukrainian industrial product sales.

The mining industry (27.2% of total sales in 2018) and metallurgical production (37.7% of sales) are the key industrial sectors of the region; they form basis of a powerful mining and smelting complex.

However, these industries are medium-low-tech. This leads to unsound technological structure, which is worse than the structure of other industrial regions. The structural and technological modernization of the region is blocked for institutional, political, functional and other reasons. At the same time, these sectors create a high

human burden on the environment and worsen the ecological and social situation in the region.

Kryvbas (Kryvyi Rih Iron Ore Basin) is the largest ore mining region in Ukraine. Mining operations form a significant amount of mineralized water that is usually discharged into natural water sources. There are different options to drain, process and use mine and quarry waters of Kryvbas, but all of them have shown to be flawed [12].

As indicated in the current Strategy for development of the region until 2020: "Dnipropetrovsk region is one of the worst in terms of access to qualitative drinking water. Most of its cities entered a pre-crisis or crisis hydrological and ecological situation because self-recovery of the Dnieper and many rivers of the basin can no longer restore the upset ecological balance. The quality of surface water does not meet requirements of economic and household consumption. One of the main problems of the region is the pollution caused by mine water" [13].

As stated by a number of regional environmental programs (e.g. the Dnipropetrovsk regional comprehensive strategy of environmental safety and prevention of climate change for 2016-2025, and the long-term program to solve the environmental problems of Kryvbas for 2011-2022) protection and sustainable use of water resources, as well as purification and processing of highly mineralized mine water are the two priority directions for development of the region.

One of the most important aspects of mine water processing is the extraction of valuable components. According to experts [14], up to 20 million m³ of highly mineralized mine water is pumped out in Kryvbas every year. Notably, this water contains bromine in such concentration that allows us to consider its industrial production.

In this work we justify the creation of bromine production from mine water of Kryvbas.

3 Extraction of bromine from mine water of Kryvbas

3.1 Market aspect

Until recently, the domestic needs of Ukraine for bromine and its derivatives were fully provided by the industrial production of bromine from the Lake Sivash brine in PJSC Brom, Crimea. According to Statista [15], Ukraine produced around 3500 metric tons of bromine in 2013. According to State Statistics Service of Ukraine, the annual revenues from bromine export were around \$ 1 mln.

However, due to the annexation of Crimea Ukraine lost its bromine production and is forced to purchase imported bromine-containing products. The resulting changes in the supply/demand balance of bromine in the domestic market actualize the idea of extracting bromine from the mine water of Kryvbas.

According to [16], about 820 000 tons of bromine are produced globally every year. Over the past 15 years the market price of bromine has increased 7 times. The

leading countries producing bromine and its compounds are USA, Israel, Jordan, China and Japan. They account for 98% of world production, see Table 1 compiled according to the data of [15, 17].

Table 1. Major countries in worldwide bromine production.

Country	Bromine production in 2018, ths tons	Bromine concentration by source, g/l
USA	- *	Brine wells – 2-6 Dead Sea brine – 10-12
Israel	190	Dead Sea brine – 10-12
Jordan	100	Dead Sea brine – 10-12
China	60	Underground wells – 0.2-0.3 Sea water – 0.05
Japan	20	Sea water – 0.05
Ukraine (temporarily occupied territory)	4.9	Shallow sea – 0.6-1
India	1.7	Lake – 3-4

*Figures for the U.S. have withheld to avoid disclosing company proprietary data.

The demand for bromine is growing (by 1-2% per year on average) because of its widespread use. Nowadays, a lot of bromine is used in production of flame retardants, which protect organic materials from ignition. A significant amount of bromine is also consumed in production of drilling fluids that are used for drilling oil and gas wells. Another area of bromine use is production of pesticides and insecticides for agriculture. Elemental bromine and its compounds are also used in water cleaning and treatment. Bromine is sometimes used for mild disinfection of pool water instead of chlorine. Other application areas of bromine compounds are pharmaceuticals and cosmetics, photographic chemicals, desiccants for cooling systems, dyestuffs, lead scavenger in anti-knock fuels, monomers for specialty polymers, bleaching and oxidizing chemicals, precision cleaning [17-19].

3.2 Technological aspect

The choice of bromine extraction technology mostly depends on concentration of bromide-ion in water. For instance, steam desorption is used to extract bromine from the Dead Sea brine, while air-desorption is used in extraction at Lake Sivash.

The concentration of bromide-ion in the mine water of Kryvbas requires the air-desorption extraction method. In this case, the main limiting stage of production is a desorption process that occurs in a countercurrent packed apparatus (desorber). For example, a titanium desorber loaded with a plastic screw packing is nowadays used in the industrial practice [20].

The high cost of titanium significantly affects the capital costs. This actualizes the search for ways to drastically reduce the size and metal/material consumption of technological equipment and, first of all, the desorber as the largest unit.

As part of a pilot project that recycles 500 m³ of mine water per hour in Kryvbas, we propose an innovative solution that greatly reduces the capital costs, see Table 2.

Table 2. Comparative analysis of the technical characteristics of traditional and innovative core equipment.

Indicators	Desorber	
	Traditional	Innovative
Material	Titanium	Titanium
Diameter, m	4.6	2.0
Packed bed	Screw-type	Screw-type
Height of packed layer, m	12	4
Irrigation intensity, m ³ /m ² ·h	30	150
Air velocity, m/s	1.4	5.7
Hydrodynamic regime	Film	Flooding
Extraction rate, %	88	88
Packed bed volume, m ³	199.3	12.6
Titanium consumption, tons	20.8	4.5

The project is based on the air-desorption method and using a critical hydrodynamic flooding regime. The latter provides an extremely high productivity and efficiency but is very unstable and may cause a technological disaster by flooding countercurrent packed apparatuses with gas/liquid emulsion. Therefore, this regime is generally considered a strict taboo.

Our innovative idea is to make the flooding regime work without disasters by making it stable both under constant and variable loads with the help of its hydraulic self-organization. The implementation of this idea was made possible due to the synergistically oriented architecture of the desorber, which has demonstrated promising results during pilot tests.

The scientific novelty consists in the new flow organization, which depending on the relative position of the desorber and fan looks as shown in Figure 1, where L – liquid flow (mine water), G_1 and G_2 – main and additional air flows, and quantitatively, G_2 is at least 3-5% of $G = G_1 + G_2$.

Such flow organization provides hydraulic self-organization of the flooding regime and makes it working.

Fig. 1. The scheme of irrigated packed bed with pumping (at the left) and suction (at the right) of air.

3.3 Economic and investment aspect

We conducted a preliminary economic assessment of constructing a bromine extraction unit. For calculations we used mine water processing volume of 500 m³/h with a mass concentration of bromide equal to 120 mg/l; the annual production capacity is 400 tons. The initial data and resulting performance of the proposed pilot project are given in Table 3.

Table 3. Pilot project performance indicators.

Indicators	Value of the indicator
<i>Initial data</i>	
Production capacity, tons per year	400
Annual sales, \$ mln	0.98
Initial investment (excluding infrastructure costs), \$ mln	0.72
Construction period, months	30
Production cost, \$ tns/ton	1.08
Risk-adjusted discount rate, %	15
Investment horizon, years	5
<i>Calculated performance indicators</i>	
Discounted payback period, months	52
Net present value, \$ mln	0.24
Internal rate of return, %	28.6
Profitability index	1.39

The implementation of this project is justified by its technical and economic indicators, the possibility of import substitution and 55 new work places that it creates. This project will diversify the country's chemical production and strengthen its economic security.

A promising option for the utilization of bromine-containing mine water of Kryvbas is production of calcium bromide, which is the main component of drilling fluids.

The traditional technology of calcium bromide production is based on reaction between liquid bromine and calcium hydroxide in the presence of a reducing agent (urea, formic acid or ammonia).

When bromine is extracted by air-desorption, the production process can be simplified and cheapened by absorbing bromine with calcium hydroxide directly from bromine-air mixture. In this case, the steps needed to obtain liquid bromine are skipped, leading to significant cost reduction of the final product [21].

In case of successful implementation of the pilot bromine extraction project, it can be scaled in order to greatly increase the production of bromine and/or its compounds. Future development of this project is associated with organization of complex processing of mine water (that contains sodium chloride, magnesium, potassium and other valuable components [14]) with a goal to obtain several target products.

The important aspects of the project are its business model and sources of financing. The lack of practical solution to the problem of mine water utilization in Kryvbas throughout years proves that it cannot be solved only with principles of market self-organization and private entrepreneurial initiative. It may be necessary to

use mechanisms of public-private partnership (PPP) or even a public-private-international partnership.

A water management industry typically has a number of factors that restrain the implementation of PPP mechanisms. As indicated in [22], these factors include: (1) high cost and unprofitability of the industry from environmental and economic standpoints, (2) low quality of source water and potentially high penalties for water pollution, (3) low profitability of the water supply sector due to underestimation of water resources.

In contrast to solutions suffering from the listed restraining factors, we suggest a project that can take full advantage of the PPP mechanisms. Our project has a socio-environmental importance, commercial effectiveness and an innovative component. Mixed financing of the project can be carried out with resources of the State Regional Development Fund, environmental funds, international technical assistance, own funds of mining enterprises, and other investors. Depending on the sources of investment, various business models can be considered to implement the project. Examples of such models are given in [23].

4 Implementing the sustainability project within a regional strategy framework

The success of any project is largely determined by the institutional framework for its implementation. Currently, significant opportunities for implementing sustainability projects with innovative components are opening up within a regional development framework.

A distinctive feature of current regional development strategies is the use of smart specialization approach. In [24], we proved that the Dnipropetrovsk region has prerequisites to form smart specialization domains based on the development of chemical production.

In line with this idea, we propose a pilot project to create an innovative import-substituting production of bromine and/or its compounds from mine water of Kryvbas as a regional development project. Table 4 shows that our project proposal meets the key criteria for prioritizing regional development projects.

The project proposal meets the objectives of Strategy for Development of the Dnipropetrovsk region until 2027: A.1.1. "Development of high-tech and innovative industries"; B.2.2. "Improving the industrial waste management system" and the smart-objective "Developing potential of the chemical complex".

In the context of this study, it is important that connecting smart and sustainable growth through smart specialization approach is possible [25]. The project proposal has a positive impact on the main dimensions of sustainable development, including social, economic, environmental and innovative dimensions, see Table 5.

The regional report "Sustainable Development Goals: Dnipro-2030" [26] specifies the region's conditions and objectives within the national Sustainable Development Goals (SDGs).

According to the expert recommendations on determining priority measures to achieve the SDGs of

the Dnipropetrovsk region, the achievement of SDG-9 “Industry, innovation and infrastructure” will be facilitated by “development of enterprises based on the newest industrial waste processing technologies and obtaining cheap raw materials for the chemical and construction industries” [26, p. 150]. Our proposed project meets these recommendations and contributes to implementation of other regional goals:

Table 4. Conformity of the project proposal with key criteria for prioritizing regional development projects.

Criteria	Compliance with criteria
<i>Significance</i>	
Alignment with the regional Strategy	The project has an obvious contribution to more than one strategic goal (program)
Impact of the project	The project has an impact on the entire region (if scaled)
Project focus	Business project with societal and environmental components
Administrative feasibility	The project provides for a partial involvement of regional authorities
<i>Readiness for implementation</i>	
Project status	There are the idea and preliminary calculation of the project
Funding	Cost structure and funding source are partially substantiated
Non-financial resources	There are scientific and technological developments, hydro-mineral resources, qualified project executors

Table 5. Impact of the project proposal on the dimensions of sustainable development.

Dimensions	Impact
Social	Creation of new jobs. Formation of new social needs and new market segments in the future
Economic	Increase in gross regional product. Production diversification. Attraction of investments. Growth of tax revenues due to a rising in the tax base. Reduction imports. Expansion the export potential of the chemical sector. Reduction budget costs for environmental activities through the production and sale of marketable products
Environmental	Reduction the negative impact of industrial waste by improving of waste management and the targeted use of local hydro-mineral resources
Innovative	Use of original innovative technical solutions that significantly reduce capital costs, increase the process efficiency and ensure the project's profitability

SDG-8 “Decent work and economic growth”: 8.1 Ensure sustainable growth of GDP / GRP through modernization of production, development of innovations, increase of export potential, promote products with a high share of added value in foreign markets;

SDG-9 “Industry, innovation and infrastructure”: 9.3.1. Increase sales of innovative products; 9.4. Stimulate the creation of technological innovations and innovative equipment of enterprises; 9.5. Ensure the provision of state financial assistance to enterprises with

technological innovations to stimulate innovative activity;

SDG-12 “Responsible consumption and production”: 12.4. Reduce the volume of waste generation and increase the volume of their recycling based on innovative technologies and production; 12.8. Taking advantage of the circular economy and closed supply chains;

SDG-17 “Partnerships for the goals”: 17.1. Mobilize additional financial resources through the promotion of investment by foreign and domestic investors; 17.2. Develop partnerships between government and business to achieve the Sustainable Development Goals.

5 Conclusions

Sustainable development of the Dnipropetrovsk region is impossible without solving a critical environmental, social and economic problem of utilization of highly mineralized mine water in the Kryvyi Rih Basin.

In this work, we proposed and justified a pilot project that produces bromine and/or its compounds from mine water of Kryvbas. The project is based on the application of authors' innovative technical and technological solutions. Other advantages of the project include use of hydro-mineral and other local resources, improved waste management, environmental focus, import substitution and development of the region's export potential.

Implementation of the project will contribute to the achievement of sustainable development goals of the Dnipropetrovsk region, notably SDG-8, 9, 12 and 17.

Rivers revitalisation: approaches to decision

Tetiana Alohkina*

Center for Problems of Marine Geology, Geoecology and Sedimentary Ore Formation National Academy of Sciences of Ukraine, Section of geology and environmental problems of ore deposits, Kyiv, 01601, Ukraine

Abstract. The article is focused on the successful implementation of the global goals of restoring water objects in the context of sustainable development that is impossible without solving the regional problems of local watercourses and reservoirs reviving. It is emphasized that awareness of riparian spaces role as ecological corridors and importance of the healthy functioning of the river network through the revitalisation of even minor watercourses leads to growth attention to this problem in an increasing number of countries. On the example of the Slepotka River in Katowice and Inhulets River in Kryvyi Rih the aspects, on which attention of revitalisation are accented in European countries and in Ukraine, are presented. In European countries, the basis for the approach to river revitalisation is their functioning as integral ecosystems. In Ukraine, nowadays, the main focus of river restoration is on cleaning them from silt sediment. In this article the approaches to decision of river revitalisation questions are presented. The main of them are: enhancing the ecological functionality of the watercourse as an ecosystem; providing flood protection; increasing the residential, cultural and recreational value; securing permanently sustainable use of watercourses and their river valleys.

1 Introduction

Nowadays science provides a better understanding of the extent to which our shared progress as human beings is undermined by the ways in which we have gone about achieving it, and too recognizes the Earth as a closely linked human-environment system. Science and technology in the modern time are powerful agents of change, depending on how and where they are headed. Increased science-policy-society cooperation can use achievement in our understanding of coupled human-environment systems and the shaping of innovative pathways towards achieving the *Sustainable Development Goals*. The fact that a large number of countries are now incorporating science, technology and innovation in their national development agenda is a promising sign [1].

Governments can lead the transformation of the world's social, economic and environmental status towards universally beneficial outcomes when guided by the Sustainable Development Goals. But they must recognize that such transformation will involve tough choices and trade-offs. There is a growing tendency for governments and companies to invest in sustainable technologies. Over the past 10 years, at least 101 economies across the developed and developing world (accounting for more than 90 per cent of global GDP) adopted formal industrial development strategies, which increased opportunities for formulating new ways to promote innovations toward sustainable development.

However, developing technology alone is not enough: technology must be made accessible and sufficiently attractive to encourage widespread adoption. Hence, in addition to research and development, the scaling up and the adoption of sustainable technologies are critically needed [1].

Understanding of an interconnection all the water resources of the Earth requires solving an issues of preservation and revival of not only the oceans and seas, but also a river network as a whole [2].

The situation of river spaces, especially of urban river spaces, in the European countries and in Ukraine, in the end of XX century, was in one sense very similar. In the context of industrialisation processes that occurred from the end of the 19th century through the first half of the 20th century, rivers and streams were used for sewage discharge, regulated and straightened for land reclamation and agricultural use, paved, channelled for flood protection (technical solutions) or even culverted. Areas by the riverside were often used commercially. Industrial zones and technical infrastructure such as roads or railway tracks were built in the floodplains. Large rivers were extended and used as waterways. During the second half of the 20th century riverside areas were subject to structural changes – industrial zones were partly abandoned, resulting in brownfields and deteriorated open spaces. Thus, up to the present day, urban river spaces suffer from lack of ecological functions (such as lack of habitat and biotope network function, lack of passability, contamination), lack of social functions (lack of accessibility of watercourses, lack of attractive open

* Corresponding author: Alohkina@gmail.com

spaces next with water, inadequate perception of rivers by the public) and other problems.

With increasing awareness of role of riparian spaces as ecological corridors and areas for social activities, active protection and restoration of such areas has been recognized as a fundamental element of measures implemented to shape the special order and sustainable development of cities. Since the 1980s, awareness of ecological issue has risen, although at different speeds in western and eastern European countries. In the western countries revitalisation and renaturation rivers began in the 1980s whereas in the central European countries it did not commence until after 1990s.

In West Germany, since 1980s an increasing number of river management projects have been developed and realised based on the insight that attention to ecological aspects of river maintenance does not hinder but can indeed play a role in improving flood protection [3, 4]. In the Eastern European countries Poland and Czech Republic, these processes did not begin until after the fall of the Iron Curtain. As for such countries as Ukraine – this practice is only beginning to appear [5, 6, 7]. Also, the potential recreational function of rivers is differently appreciating in the West and East.

In densely populated and industrialised areas, revitalisation of urban river areas contributes to a high quality of the environment as well as to a high quality of life. Urban river spaces are often the only functioning or potential reservoirs of biodiversity and open spaces in cities. Thus, the active protection and restoration of such areas is part of the repertoire of fundamental practices for shaping cities' spatial order and *sustainable development*.

The *aim of our work* was a comparative analysis of approaches to river revitalization, which are used in the European Union countries and in Ukraine. As examples, the Slepjotka River in the Polish city of Katowice and the Inhulets River in the Ukrainian city of Kryvyi Rih were selected.

River revitalisation is not just about rivers. The preparation and implementation of a revitalization project is not limited to technical questions of hydraulic engineering but touches all aspects of sustainability.

Issues related to the restoration of river ecosystems can be considered from different angles. In our country, the revitalization is most often understood as a process of bottom dredging, which is necessary either for shipping purposes or in the context of the removal of contaminated sediments. Whereas in European practice much more attention is paid to restoring the hydrodynamics of the watercourse, the formation of characteristic ecotopes, as well as the recreational component.

The concept of revitalization was formulated by V. K. Khilchevsky [5, 6]: "This is the complete restoration of watercourses or certain sections thereof at the level of the river's existence, which preceded the industrial development of this region; when the river network was undisturbed and no centralized or point sewage discharges were made".

The issues of rivers revitalization in Ukraine at the state level are not yet considered comprehensively. The focus is on aspects such as dredging to improve shipping or the comprehensive programs for the elimination of

consequences of flooding in the cities and towns of Ukraine. The latter is the Cabinet of Ministers of Ukraine resolution of 15.02.2002 No. 160.

In last years the processes of the bottom purification and dredging are activated in different regions of Ukraine. Cases of fragmentary manifestation of elements of modern river revitalisation are beginning to emerge at the level of urban communities. So, in Lutsk, elements of revitalization of the Saralavka River – the right tributary of the Styr River was accomplished in 2013-2014 years [7]. The work was carried out on a small plot of 0,5 km in the central part of the city jointly by the city authorities and business structures. A revitalisation project consists of many different tasks and requires the cooperation of many different experts and also laypeople, who are convinced of the project's success.

2 Objects and actions

Current planning methods in the European countries and in Ukraine have an impact on the implementation, realisation and acceptance of urban river revitalisation projects. Legal and technical regulations, generally available information and information provided by local, regional and state authorities as well as the development of planning criteria, the "planning philosophy" and the self-understanding of landscape architects and town planners all affect the outcomes of urban river revitalisation projects.

Below, the certain aspects and approaches to the revitalization of the Slepjotka River in Katowice and the Inhulets River in Kryvyi Rih are presented. We will consider the main points on which attention was focused in the projects, of which the author was a participant.

It is well known that the basis of large rivers water balance is a flow of small rivers. Small rivers hydrology, hydrochemistry, water quality is closely related to local geological-geomorphological, soil-plant conditions and anthropogenic processes that occur at a specific catchment. The formation of small rivers and their basins is determined by the surface runoff from regional landscape complexes, therefore an effect of natural and anthropogenic factors on such sites manifests faster and more clearly. It makes ecosystems of small rivers more vulnerable both a result of the direct impact on them of pollutants and indirect influence.

Transformation of Slepjotka River in Katowice.

Katowice is a city in southern Poland, where in mid-18th century was discovered rich coal reserves. In the first half of the 19th century intensive industrialization transformed local workshops into industrial steelworks, mines, foundries. Now Katowice is a large coal and steel centre. For decades if not a century, in this region, rivers and streams were regulated and straightened for land reclamation and industrial use. They were paved or even tubed. For a long time, streams of all scales were adopted to discharge excess water and sewage. The regulation and channelisation of river beds, construction of drainage works and the implementation of active flood protection contributed to degradation of the river valleys.

The main goal of the revitalization action in Katowice was to recreate a blue-green river valley corridor in the highly urbanized, mid-part of Slepjotka River [8]. This particular stretch of the river was chosen for special, ecological and social reasons. The local catchment features numerous forms of land use and an advantageous land-owners structure, since most of the riparian area was municipal property. This river has quite suffered from the discharge of untreated sanitary sewage, but the flood risk was insignificant (figure 1). Additionally, it was located in the neighbourhood of a large housing estate in the direct Ochojec in the centre of Katowice. Access to the river and recreational facilities would improve the living conditions for thousands of inhabitants in the adjacent area. Thus, public support for the idea of revitalisation was high.

Fig. 1. Slepjotka River before transformation [8].

The authorities of Katowice city wanted to integrate the concept of a river corridor into special planning and management practices in post-mining urbanized areas, to re-establish a green axis along the river valley and to enlarge the public open leisure space. Furthermore, semi-natural wetland was to be created in order to increase the retention capacity and amphibious as well as water habitats and to establish a new paradigm for urban water management.

The revitalisation project on the Slepjotka River in Katowice is the opportunity to illustrate ways to implement the proposed transformation of the complete corridor of Slepjotka River. Not only did they want to increase the habitat diversity, establish a stable plant cover by using native plant species, and re-establish riparian forest, dry forest and wetlands habitat. They also aimed to show applications of soil bioengineering methods in order to establish buffer-zones that would protect the river from contaminations (figure 2).

The project included, among other things, the reconstruction of 210 m² of the dry old river bed and 950 m² of the wet old river bed, formation of a sand dune, construction of wooden bridges across the river and the old river bed, and setting-up of information boards.

The Slepjotka River action achieved several goals: The planned revitalisation was successfully implemented and the pilot action served as a very good starting point for preparation of the valley development plan. Most of the expectations of the City of Katowice and the researchers at the Central Mining Institute concerning

revitalisation effects, development of habitat diversity and land use transformation were fulfilled. Moreover, the river corridor concept developed and tested in the pilot action area proved to be suitable for implementation along other parts of Slepjotka River and even at sites along other rivers.

Fig. 2. Slepjotka River after transformation [8].

Public involvement proved to be one of the most important aspects of the Slepjotka River revitalisation that had not been discussed previously. The City of Katowice as the coordinator of public participation and cooperation managed to involve numerous actors.

Besides city representatives, administrative partners included managers of the Slepjotka Valley, educational institutions as well as maintenance and safety services. Several universities and research institutes also participated in the partnership. Furthermore, the local community and private land owners from Slepjotka valley, NGOs, architects, artists, historians, and the media, among others, participated in workshops and meetings on the development of a long-term vision for the Slepjotka valley.

The workshops proved the potential of institutional, public, private and research-based cooperation and resulted in models of cooperation for the river valley partnership that increased the problem-solving competences by combining interests and ensuring the convergence of goals. Thus, public participation procedures helped to develop a coherent vision of spatial management for Slepjotka valley and led to overall satisfaction in the local community.

Riverbed purification in the Inhulets River in Kryvyi

Rih. Kryvyi Rih is the largest iron ore mining and processing centre in Ukraine. The territory, where from narrow meridional strip 1,0–3,0 km wide and 100–150 km long, has mined 2,2–2,8 billion tonnes of chemically pure iron over the last 125 years [9]. Undoubtedly, long-term and large-scale man-made activity in this region has reflected on all components of the biosphere: lithosphere, atmosphere, hydrosphere. Technogenic origin products are constantly occur in compound of rivers sediment which flowing through this territory: particles of metallurgical slag, sludge, tailings of ore-dressing and other wastes. And the rivers look more like sewage gutter.

The accumulation of environmental problems and the consequent increase in community dissatisfaction has

prompted city authorities to seek solutions to the situation. At the same time, community awareness of the role of river valley as a network of environmental corridors and places of social activity was increased.

In 2014, the Dnipropetrovsk Regional Water Resources Administration entered an agreement with the private enterprise “Universalgasbud” for the implementation of the project “Anti-flood measures and improvement of the hydrological status of the Inhulets River in Dnipropetrovsk region”.

The main purpose of the planned activities was implementation the Cabinet of Ministers of Ukraine resolution from 15.02.2002 No 160 “The comprehensive program for the elimination of consequences of flooding in the cities and towns of Ukraine”. And also an implementation the regional program “The elimination of the effects of flooding the territory in cities and towns of Dnipropetrovsk region for the period till 2030” which was approved by the decision of the regional council of July 18, 2003 No 184-9/XXIV.

Among other works, significant of works were planned to clean up the Inhulets River in different parts of the Kryvyi Rih city. A project was planned to clear up 4,3 km of the riverbed and 0,5 km an old tributary of the Inhulets – the Saksahan River. Elements for a revitalization of the Inhulets River section and it tributary of Saksahan River, in the central part of the city in the park area, were implemented. The works included the riverbed purification, clearing the banks, arranging the territory (figures 3, 4). Sediment, removed from the river, was mainly deposited at landfills. The works which carried out in the city centre contained elements of revitalization, but the main goal was not done – to restore the flow of the river. The cleared areas are little flowing part of the riverbed.

Fig. 3. Works for purification of the Saksahan River [10].

The main goal of the second stage of works the riverbed purification in the Inhulets River (in 2017) was the removal of a large amount of contaminated sediment. Contaminated sediment was formed as a result of activity the ore-dressing factories and the metallurgical plant, which are located higher on the river flow. The initiative to carry out these works came from community of a nearby area.

During dredging and purification operations, a significant amount of subaquatic polluted and man-made transformed sediment was raised to the surface. A method of carrying out the cleaning operations included lifting of bottom silt in a semi-liquid state with the help of a dredge

and burying it in ditches, which were located on the low bank of the river at a distance of 10-20 m from the river bank (figures 5, 6). The issues of storage and/or burial of the raised sediment are relevant and important, because it contains significant concentration of heavy metals, radionuclides and other pollutants.

Fig. 4. The intermediate stage of revitalisation project on the Saksahan River [10].

Fig. 5. Inhulets River. Stage of bottom purification (author's photo).

As you can see from the photo (figure 6), the ditches bottoms did not have any waterproofing, so in a short time a variety of pollutants (including heavy metals) can return end up in the river again. Also, there is a constant washing away of the upper soil layer, because after the backfilling of the ditches, phyto-recultivation works were not implemented.

3 Analysis and discussion

Thus, the features of the implementation of river revitalisation works of the Slepotka River in Katowice and the Inhulets River in Kryvyi Rih were presented.

Environmental aspects and nature conservation have only gradually become incorporated into legal and regional programs; as a consequence, this contributes to reducing water pollution and tackling river revitalisation.

Fig. 6. Inhulets River. Ditch along the river which intended for burial of sediments (author' photo).

The main tasks of the revitalisation in European countries, and in Poland in particular, are questions of flow restoration, improved hydrodynamics, self-purification and ecosystems restoration. In the same time, the main goal of the revitalisation in Ukraine are still the issues of purification the riverbed from silt or questions relevant to preventing flooding. And on large rivers, the main problem of cleaning operations is the restoration of navigation. In rare cases, the purpose of revitalisation is to increase the recreational attractiveness of the territory (most often we are talking about the central areas of cities).

Waterfront areas, were often used commercially, start to using more and more as recreational zones. However, industrial zones and technical infrastructure such as roads or railways tracks, factories are staying in the floodplains. Even after industrial utilisation of inner-city began to decline, riparian post-industrial areas are still left abandoned. The visual and functional attractiveness of rives as well as the perceptibility of water courses are low. Public access to the river continues to be of little importance as are its ecological functions.

Here we will try to lay out main aspects of successful river revitalisation. One of the main aims of revitalisation addresses the enhancement of the ecological functionality of the watercourse. Secondly, river revitalisation is a means to implement flood protection. Onwards, it contributes to increasing the residential, cultural and recreational value of the area, and finally, it helps to secure the permanently sustainable use of watercourses and their flood plains.

From the experience such countries as Poland, Czech Republic and Germany [3, 4, 8, 11-14] and the own experience a participation in a some revitalisation projects [8, 9, 15] have been developed the following approaches for urban river revitalization. The approaches are intended to help planners, decision-makers, executing authorities and stakeholders consider the wide range of aspects (ecological, economic and social) relevant to the specific requirements of river revitalisation in an urban

environment. The approaches are divided into four basic groups which are shown on the scheme (figure 7). Each of these four basic components consist of a range of issues.

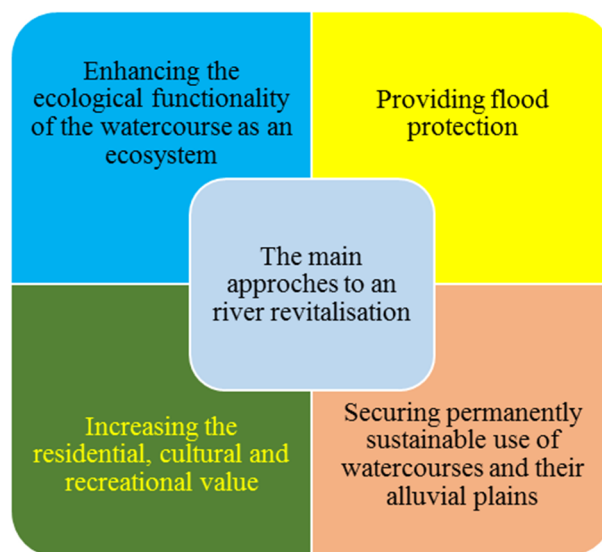

Fig. 7. The scheme of an approaches to a river revitalisation.

Enhancing the ecological functionality of the watercourse as an ecosystem can include next aspects:

- Renewal the hydrodynamic regime of watercourses. It can be achieved by increase the morphological diversity of the riverbed as well as the discharge diversity and its dynamics; by modify of the sediment regime through a suitable longitudinal profile of the watercourse.
- Renewal minor watercourses can be done by to remove the channeled underground stretches of the watercourses and prevent further channeling; by deepening a shallow section of riverbeds; if possible, by re-meander straightened river beds in minor watercourses, according to their historical development.
- Improve the water quality can by support the self-cleaning capacity of watercourses; by addition water infrastructure (build separated sewer systems, wastewater treatment plants); by pre-treat rainwater before it reaches the river. One of the main solutions – to eliminate pollution sources.
- Increase the biodiversity of the biotopes in river valley can achieved by improve local habitats according to the local conditions of each river valley; by remove invasive plant species; by support the reintroduction of native plant species and habitats.
- Assurance migration permeability of watercourses can be achieved by build fish passes; by provide migration permeability by transversal objects (stepped weirs and chutes), and technical alterations (shallow water column and high flow speed) to the watercourse.

Need to give an advantage nature-like adaptations over technical modifications to the landscape.

Providing flood protection can include next aspects:

- Mitigation the risk of flood damage with help: adopting the idea that rivers need more space; need to

avoid artificial elevation of terrain due to building development in active flood zones.

- Increase the retention capacity of the landscape can be achieved by allow the natural overflow of rivers into the alluvial plains; need to renew and create wetlands, where it is possible; to implement elements of the systems of ecological stability.

- Reducing direct outflow from the drainage area (especially important for small watercourses) by the increase the rate of rainwater infiltration in the area by allow its infiltration into the soil profile; reuse excessive rainwater in households and the municipal sector.

- Implementation technical measures to catch extreme flow rates: use retention tanks and dry polders in the river valley.

Increasing the residential, cultural and recreational value may be consist of next elements:

- Incorporate water into the city's image as a major landscaping feature of the urbanised space. So, we can use the alluvial plains as significant urban spaces with a unique potential for recreation and leisure.

- Access to the water as a security and pleased moment to leisure: building play facilities providing interaction with the water element; provide possibilities for fishing; allow direct public access to the watercourse in some places where it is safe and possible.

- Creation sport and recreational paths (greenways) along watercourses. Creation or combination paths for pedestrians, cyclists, in-line skaters and other non-motorised users, following the terrain in the alluvial plains. Improve a connection of the city with the surrounding landscape

- Building sport and recreational facilities in the alluvial plains. Creation places for short-term recreation of the public along the sport and recreational paths.

- Ability to provide supplementary infrastructure. Building an information system along the sport and recreational paths (signposts, information boards, panels along educational paths providing information about natural and cultural features and values in the area). Installation street furniture; presentation artefacts and temporary exhibitions.

Securing permanently sustainable use of watercourses and their river valleys can be achieved:

- By improving the applicability of the land use planning process in terms of flood control and watercourse protection. Need to use the instrument of land use planning to apply the above-mentioned principles in the revitalisation of watercourses in urbanized areas. Need to develop more detailed rules for the use of built-up areas concerning the risk of potential.

- Set rules for water withdrawal to secure a sufficient flow volume for maintaining the dynamic water regime of watercourses.

- Minimise conflicts with infrastructure (bridges, roads, pipelines).

Main steps of successful river revitalisation include: planning (with all stakeholders' involvement), implementation, scientific and educational compound, public relations activities and financing.

Planning. It is very important to consider the aims and requirements of sectoral planning (especially plans and regulations of the water management authorities, nature conservation management authorities and land use management authorities) and of spatial planning and include the revitalisation project in these aims. So need to have the revitalisation project incorporated into the relevant region and local spatial management plan, especially if the project is not limited to a single site but will affect the whole course of a river or a creek within the city or urban spaces with adjacent river banks and flood plains. In this way the project will be protected authorities and will have to be taken into account in subordinate planning. Additionally, an environmental impact assessment might be required. On the figure 8 a planning model of the river revitalisation is introduced.

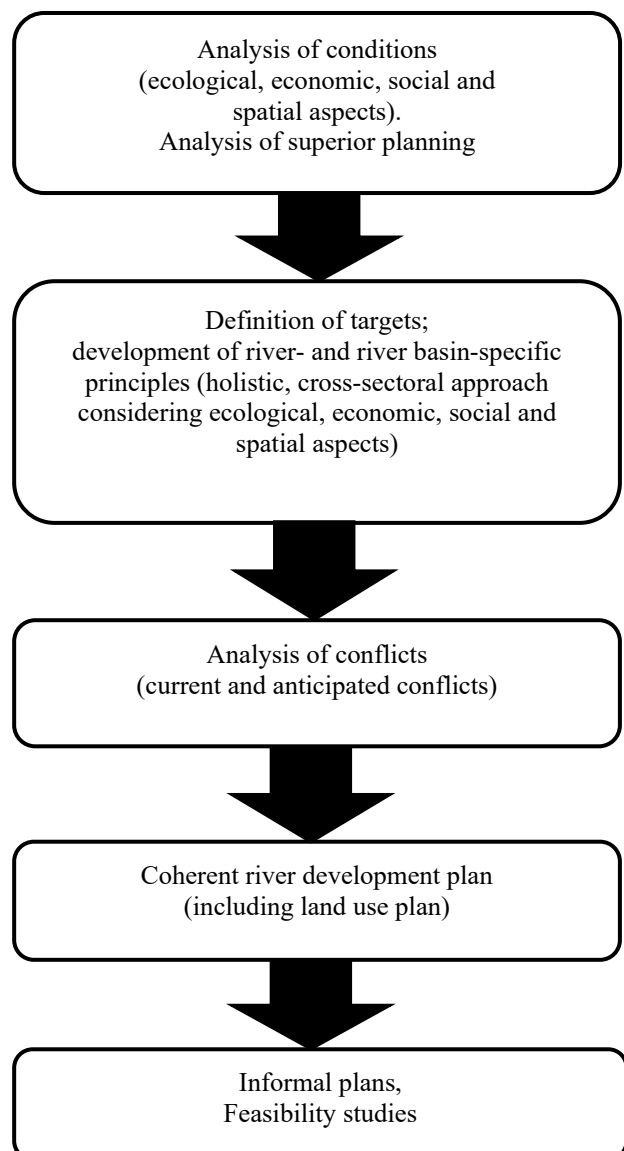

Fig. 8. Scheme of planning the river revitalisation activities.

Furthermore, improving the availability, visibility, attractiveness and safety of riverside areas has to be incorporated into the revitalisation project; secure access to the water and continuity of waterside routes should also be ensured. Waterfronts are socially as well as

economically important determinants of a city's attractiveness.

A combination of necessary (flood protection) and desirable activities fosters public and also political acceptance of urban river revitalisation measures.

Implementation. Preferable, start revitalisation of a river or stream from the upper reaches downstream. Otherwise, the current emerging from a paved stretch and encountering the stronger coarseness of a renaturated stretch may develop strong erosive forces and require comprehensive pavements in the transition area. Upstream drainage conditions always determine the flood prevention measures in the territory considered for revitalisation.

The surveys of the project area must be thorough and qualified. Need to eliminate sources of pollution in the catchment area as a precondition for proper revitalisation and increase the self-cleaning capacity of water bodies. Ensure that construction is supervised with respect to ecological issues so that the goals are met.

Take a priority bio-engineering measures rather than technical solutions.

Scientific and educational compound of the river revitalization project and public relations activities. A prerequisite for a successful project should be a comprehensive study of the ecology of the river. Attracting educational institutions will help not only to collect the necessary information, but also increase the knowledge of schoolchildren and students about the features of the region. It is possible to provide an implementation public education programs and improve training in revitalisation principles that target different social groups.

A significant role is efforts to secure positive media coverage and public perceptions of the project by implementing an on-going information campaign for the project. Remember to use always the same logos and graphic design. It is very important to promote the project and its benefits by organizing events, celebrations, ground-breaking ceremonies, inaugurations, guided tours, leaflets, press relations, exhibitions, display boards, etc. Raise awareness of the manifold benefits of revitalisation project promotes successful implementation of it. So it is important to disseminate information about good and best revitalisation practices examples among decisionmakers and the general public.

Financing. Including solutions to water management tasks in the revitalisation project makes its funding and implementation more likely.

It is important to respond quickly to available funds is a frequent experience in public administrations, as payments from environmental impact mitigation regulation or other fees may suddenly become available or funds have to be spent before the fiscal year ends.

Endeavour to find adequate co-financing, because the municipal budget is characterised by fundamental restrictions in many places. Analyse opportunities for dividing the project into several stages that are realised step-by-step and financed from different sources. Obtain information on possible grants from various sources. Find institutions (sponsors) that are able to make a permanent contribution to the project, even if it is small (particularly

during maintenance). Use impact mitigation regulation / impact mitigation fees to finance revitalisation projects. Explore possibilities for private funding (e.g. foundations, Private-Public-Partnerships, sharing costs with private developers).

Try to consider the costs as completely as possible in order to avoid miscalculation. Budget enough funding to allow for good planning and maintenance. A river revitalisation project can be sustainable only if the investment is well prepared during the planning phase and if future maintenance is assured. Try to reduce maintenance costs. Maintenance costs can get expensive and are often not taken into account at the start of a project. Factor in enough funding to cover unforeseen minor and major changes during the construction work. Calculate enough funding to provide adequate resources for public participation.

4 Conclusions

1. The successful implementation of the global goals of restoring the Earth's water objects in the context of sustainable development is impossible without solving the regional problems of local watercourses and reservoirs reviving. Awareness of riparian spaces role as ecological corridors and areas for social activities and also of the importance of the healthy functioning of the river network through the revitalisation of even minor watercourses leads to growth attention to this problem in an increasing number of countries. Ukraine, as an integral part of the world community, is striving to restore its water resources and revive rivers.

2. Current approaches to solving the problem of river revitalization have their differences in different countries. These differences are based on the purpose of using a watercourse. In European countries, the basis for the approach to river revitalization is their functioning as integral ecosystems. The result of this approach is an attempt to maximize the restoration of the river to its natural state, minimize the anthropogenic pressure, harmonize the relationship between people and nature. In Ukraine, today, the main focus of river restoration is on cleaning them from silt sediment. At the same time, the following goals are being pursued: of an economic nature – the restoration of river navigation; flood control measures; solving a number of environmental problems. However, the latter are often not prioritized and, as a result, the real tasks of restoring hydroecosystems are not fully resolved.

3. Based on the analysis of participation experience in various river revitalization projects, the main approaches to solving this problem are presented and characterized: 1) Enhancing the ecological functionality of the watercourse as an ecosystem; 2) Providing flood protection; 3) Increasing the residential, cultural and recreational value; 4) Securing permanently sustainable use of watercourses and their river valleys. The main stages of the implementation of river revitalization projects, especially in urban areas, are presented, and ideas are proposed for a comprehensive consideration of emerging problems.

Abstract. This research was performed at Petrovsky waste rock dump, the Central part of the Kryvyi Rih iron-ore & metallurgical district (Dnipropetrovsk region, Ukraine). The macronutrients (K, Ca, Mg, P and S) and heavy metals (Fe, Mn, Zn, Cu, Pb and Cd) contents in the leaves of three species of the trees (Ash-leaved maple, Silver Birch and Black locust) that were collected on devastated lands were assessed. It was established that trees which grow on the Petrovsky dump take place under evident shortage of nutrients (especially K and P) and excess of metals (especially Fe, Mn and Zn). It is revealed that Ash-leaved maple and Black locust are more resistant to the geochemical conditions of devastated lands. In this regard, these species of trees can be recommended for forest restoration & reforestation on devastated lands.

1 Introduction

Devastated lands, formed as a result of human activity, occupy vast areas: more than 2,000,000 ha worldwide, about 200,000 ha in Ukraine and about 100,000 ha in Germany [14, 16, 21]. These lands are as pollution sources for the atmosphere, soil, surface water. They are also sources of distribution of weeds [7, 22, 23]. Therefore, devastated lands pose a serious threat to human well-being. Currently, planting trees is the most promising way of restoring devastated lands [1, 19]. However, on these lands the ecological conditions are very strict for trees [7, 21, 18, 22, 31]. Therefore, investigation of chemical composition of trees that naturally grow on devastated lands is very important.

The object of this work: to carry out a comparative analysis of macro nutrients and heavy metals contents in the leaves of trees spontaneously sprouting on the devastated lands at the Kryvyi Rih District.

2 Materials and methods

The results of the studies, which were carried out at Petrovsky waste rock dump (Fig. 1) in Central part of the Kryvyi Rih District (Dnipropetrovsk region, Ukraine), were used as the materials for this paper.

Petrovsky waste rock dump was formed for storage: 1) low-prospective iron ores, 2) quartzites 3) shales 4) loose rocks (clay, sand and loam). On this dump the ecological conditions for growth and development of woody plants are typical for Kryvyi Rih region [7]. It is based on the structure of mine rocks, dump's age (about

50 years) and dump's area (26 ha). Territories located for 30 km apart from industrial facilities and stationed in Gurovsky forest were used as control site.

Sampling of leaves from three species (Ash-leaved Maple *Acer negundo* L., Silver Birch *Betula pendula* Roth. and Black Locust *Robinia pseudoacacia* L.), drying and grinding of them were performed in the fall of 2019 by classical methods [5, 10, 11, 24].

For the sample preparation, to the leaf sample weight of 100 mg 0.2 ml of H₂O DI and 1.6 ml of HNO₃ (65%) were added. The solution was incubated at room temperature during 24 hours. Then, 0.6 ml of HF (4.8%) and 0.9 ml of HCl (36%) were added to this solution. Subsequently, the solution was placed in the microwave oven (Mikrowellen-Laborsystem, MLS-ETHOS plus). The microwave exposure was continued during 2 hours. Next, H₂O DI was poured into, diluting the volume of solution to 10 ml. Finally, 0.1 ml of Internal Standart was poured to 1 ml of mineralizate collected, after which H₂O DI was poured again diluting the volume to 10 ml.

The final determination of macronutrients (K, Ca, Mg, P, S) and heavy metals (Fe, Mn, Zn, Cu, Pb, Cd) concentrations was performed using the Inductively Coupled Plasma Mass Spectrometry (ICP-MS X-Series instrument 2, Thermo Fisher Scientific, USA).

The analytical part of our research was performed on laboratory base of the Institute of Biosciences, Freiberg Mining Academy and University of Technology (Freiberg, Germany).

The obtained results of macronutrients and heavy metals content in the leaves of trees were calculated in mg*kg⁻¹ of dry weight (mg*kg⁻¹ d.w.). Then the results were processed by standard methods of variational

statistics at the significance level of $p < 0,05$ [17].

3 Results

3.1 Macronutrients and heavy metals content in leaves at a control site

According to scientific literature [6, 8, 9] the Potassium average content in plants is in the range from 7 500 to 15 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w. We found that in a control site the values Potassium concentration in the leaves of Birch and Black locusts leaves were below these this range. While, in the maple leaves Potassium concentrations were appeared to be within this range (Table 1). The average Calcium concentrations in plants are from 12 500 to 18 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w. [6, 8, 9, 12]. By the results of our research, Calcium content in the Birch leaves is within this range, while in the leaves of Black locust and Maple the examined value is above this limit. The analysis of scientific literature shows, Magnesium contain in the plants is 1 000-3 200 $\text{mg}\cdot\text{kg}^{-1}$ d.w. [6, 8, 9, 12]. At a control site, the Magnesium concentrations in the leaves of all of three tree species slightly exceeded the values of the range pointed above.

The average concentrations of Phosphorus in plants are 1 750-2 300 $\text{mg}\cdot\text{kg}^{-1}$ d.w. [6, 8, 9, 20]. Phosphorus content in the leaves of all of tree's species at control site is below the values of this range. According to the scientific literature [6, 8, 20], the average Sulfur content is from 7 500 to 14 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w. We found that in control territories the Sulfur concentrations in the leaves of all the trees were below the values of this range (Table 1).

Thus, the Calcium and Magnesium content in the leaves of trees from a control site is within the average values established for all the vegetation. In our opinion, this phenomenon may be due to the regional biogeochemical features of Kryvyi Rih iron-ore & metallurgical district. As it is well known, in this region, the increased content of these macronutrients was detected in all the objects of Nature: soil, groundwater and surface water.

Kryvyi Rih City Map

Kryvyi Rih

Petrovsky Waste Rock Dumps Map

Fig. 1. Location of study areas (I, II, III, IV, V – Study Plots)

Phosphorus and Sulfur concentrations in the leaves of trees from a control site were below the range values of these elements in all vegetation. This consistent pattern can be explained by the seasonal dynamics of nutrients concentration in the leaves of trees.

Average Ferrum content in all vegetation is 200 $\text{mg}\cdot\text{kg}^{-1}$ d.w., while in the leaves of trees that have grown outside by influence of industrial enterprises this metal content is 150-350 $\text{mg}\cdot\text{kg}^{-1}$ d.w. [2, 9, 12]. At a control site the Ferrum content was found at the same

interval in the leaves of Birch and Black locust. Whereas, in the leaves of Maple a Ferrum concentration was slightly higher than this interval values (Table 2).

Table 1. Macronutrients content in the leaves of trees from a control site.

Species of trees	Macronutrients content, mg*kg ⁻¹ of dry weight		
	M	m	CV%
<i>Potassium</i>			
Ash-leaved maple	10 110	192,09	28,46
Silver birch	4 633	184,00	21,41

Black locust	0,003	0,001	32,45

M – arithmetic mean, m – standard error of mean, CV% – coefficient of variability.

The average Manganese content in all vegetation is 200 mg*kg⁻¹ d.w. [9, 12, 20]. We found that at a control site in the leaves of all tree species, the concentrations of this metal were well below than this range. Zinc concentrations in vegetation are around 30 mg*kg⁻¹ d.w., and in the leaves of trees that have grown outside by industrial enterprises influence, they are at range 25-50 mg*kg⁻¹ d.w. [8, 9, 12, 20]. According to our research, Zinc content in Birch leaves is within the same range. It should also be noted that the concentrations of this metal in the leaves of Black locust and Maple were significantly lower (Table 2).

In the Vegetation of the World, the average Copper contain is about 8 mg*kg⁻¹ d.w. [9, 12, 20]. We found that the concentrations of this metal in the leaves of all tree species were significantly below this level. Average Lead content in the vegetation is around 1,25 mg*kg⁻¹ d.w. [9, 12], and in the leaves of trees it is at the level of 0,5-1,0 mg*kg⁻¹ d.w. [12, 20]. The analysis of obtained results shows that at a control site the concentrations of this metal in the leaves of all the investigated tree species were below these values (Table 2).

The similar consistent patterns were found for Cadmium concentrations. In all the vegetation its content is 0,03-0,05 mg*kg⁻¹ d.w. At a control site, the concentrations of this metal in the leaves of all the tree species were below these values (Table 2).

Thus, at a control site in the leaves of the trees, the only Ferrum and partially Zinc concentrations lie within the range of average values established for the vegetation. While, the concentrations of other metals (Manganese, Copper, Lead and Cadmium) are 2-7 times lower than the average values. In our opinion, this phenomenon can be explained by the effect of regional geochemical and biogeochemical anomaly, which is characterized by the increased content of Ferrum and Zinc. In addition, we believe that casual autumn dynamics of chemical elements in plants has the effect on the concentration of heavy metals in the leaves of trees.

3.2 Macronutrients and heavy metals content in leaves at a devastated lands

In the devastated lands at Kryvyi Rih iron-ore & metallurgical district, the content of Potassium in the leaves of the trees is less than control values (Fig. 2).

We found that, in the leaves of trees from the devastated lands at Kryvyi Rih region Potassium concentrations were less than the control values in Maple – by 15-70% ($p < 0,05$), in Birch – by 15-55% ($p < 0,05$). In the leaves of Black locust, both potassium content reduction (plots II III – by 10-45% ($p < 0,05$) less) and accumulation of this element (plots IV – by 20% ($p < 0,05$) higher) were detected.

Calcium content in the leaves emerged below than control values too (Fig. 2): in Birch – by 19-54% ($p < 0,05$) and in Black locust – by 51-62% ($p < 0,05$). It should be noted that the concentrations of this metal in Maple's leaves at the plots II, IV, V were at the level of control values, while at the plot III they were by 40% ($p < 0,05$) less than the control values (Fig. 2).

Fig. 2. The relative K, Ca, Mg content in the leaves of trees from the devastated lands at Kryvyi Rih district. The element content in the control is 100%. Research areas: C – control, I, II, III, IV, V plots on devastated land. Acer – Ash-leaved maple, Betula – Silver Birch, Robinia – Black locust.

The analysis of obtained results (Fig. 2) shows that the Magnesium content was both higher and lower than the control values. Thus, in the leaves of Birch the accumulation of this element is predominant, the excess of control values is by 25-70% ($p < 0,05$). In Maple's leaves, Magnesium concentrations at plot II were by 14% ($p < 0,05$) above control and at plots I and III they were 10-55% ($p < 0,05$) less than control values. The content of this element in Black locust's leaves was within the control values (plots II and V) or by 17% ($p < 0,05$) less (plot II).

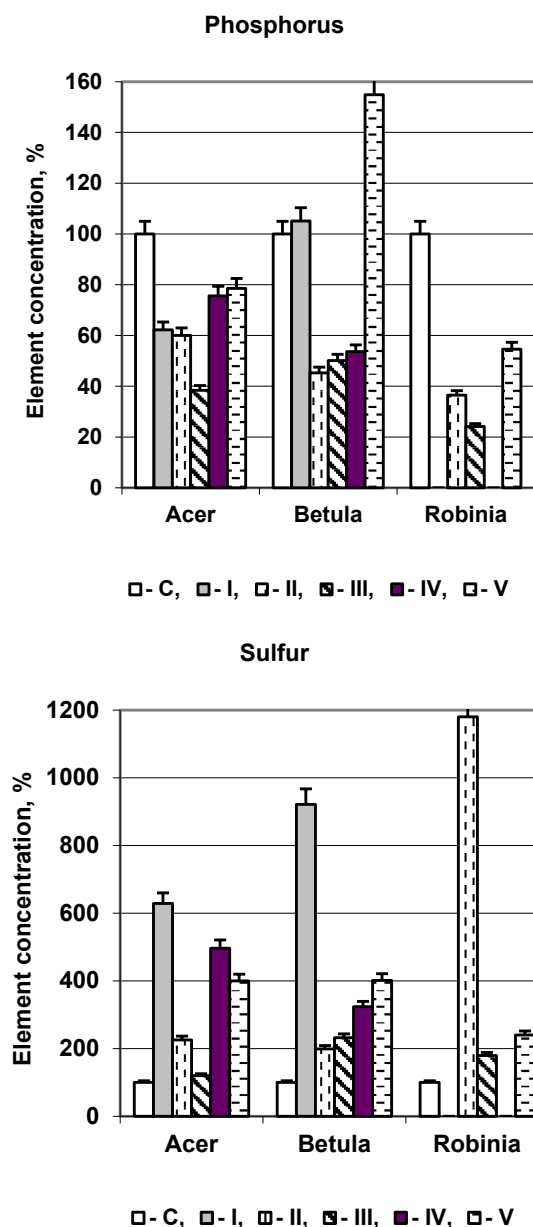

Fig. 3. The relative P и S content in the leaves of trees from the devastated lands at Kryvyi Rih district. The element content in the control is 100%. Research areas: C – control, I, II, III, IV, V plots on devastated land. Acer – Ash-leaved maple, Betula – Silver Birch, Robinia – Black locust.

It was found that the Phosphorus content in the leaves of trees from devastated lands at the Kryvyi Rih region was less than control values (Fig. 3): by 21-61% ($p < 0,05$) for Maple and by 46-63% ($p < 0,05$) for Black locust. The content of this element in the Birch's leaves in most cases (plots II, II, IV) was below the control values by 44-54% ($p < 0,05$), but at the plot V it emerged by 55% ($p < 0,05$) higher than the control value.

The analysis of obtained results shows that in the leaves of trees from the devastated lands at Kryvyi Rih region only accumulation of Ferrum is statistically significant (Fig. 4). Thus, the concentrations of this metal in the leaves were higher than the control values: in Black locust by 1,7-2,4 times ($p < 0,05$), in Birch by 1,9-4,0 times ($p < 0,05$), in Maple by 1,2-5,0 times ($p < 0,05$).

Manganese content exceeds the control values in Black locust leaves (by 2,7-8,1 times ($p < 0,05$)) and in Birch (by 13-49 times ($p < 0,05$)). While, in the Maple leaves, both accumulation of this metal (at plots I and II by 1,5-1,7 times above the control ($p < 0,05$)) and its “leaching” (at plots III and IV by 15-19% below control ($p < 0,05$)) were found.

In most cases, the Zinc contents in the leaves of trees were higher than the control values: by 11-19% ($p < 0,05$) in Maple, by 1,4 times ($p < 0,05$), in Black locust and 1,7-3.2 times ($p < 0,05$) in Birch. It was also found that at plot III concentrations of this metal were below the control values: in Maple by 37% ($p < 0,05$) and in Black locust by 48% ($p < 0,05$).

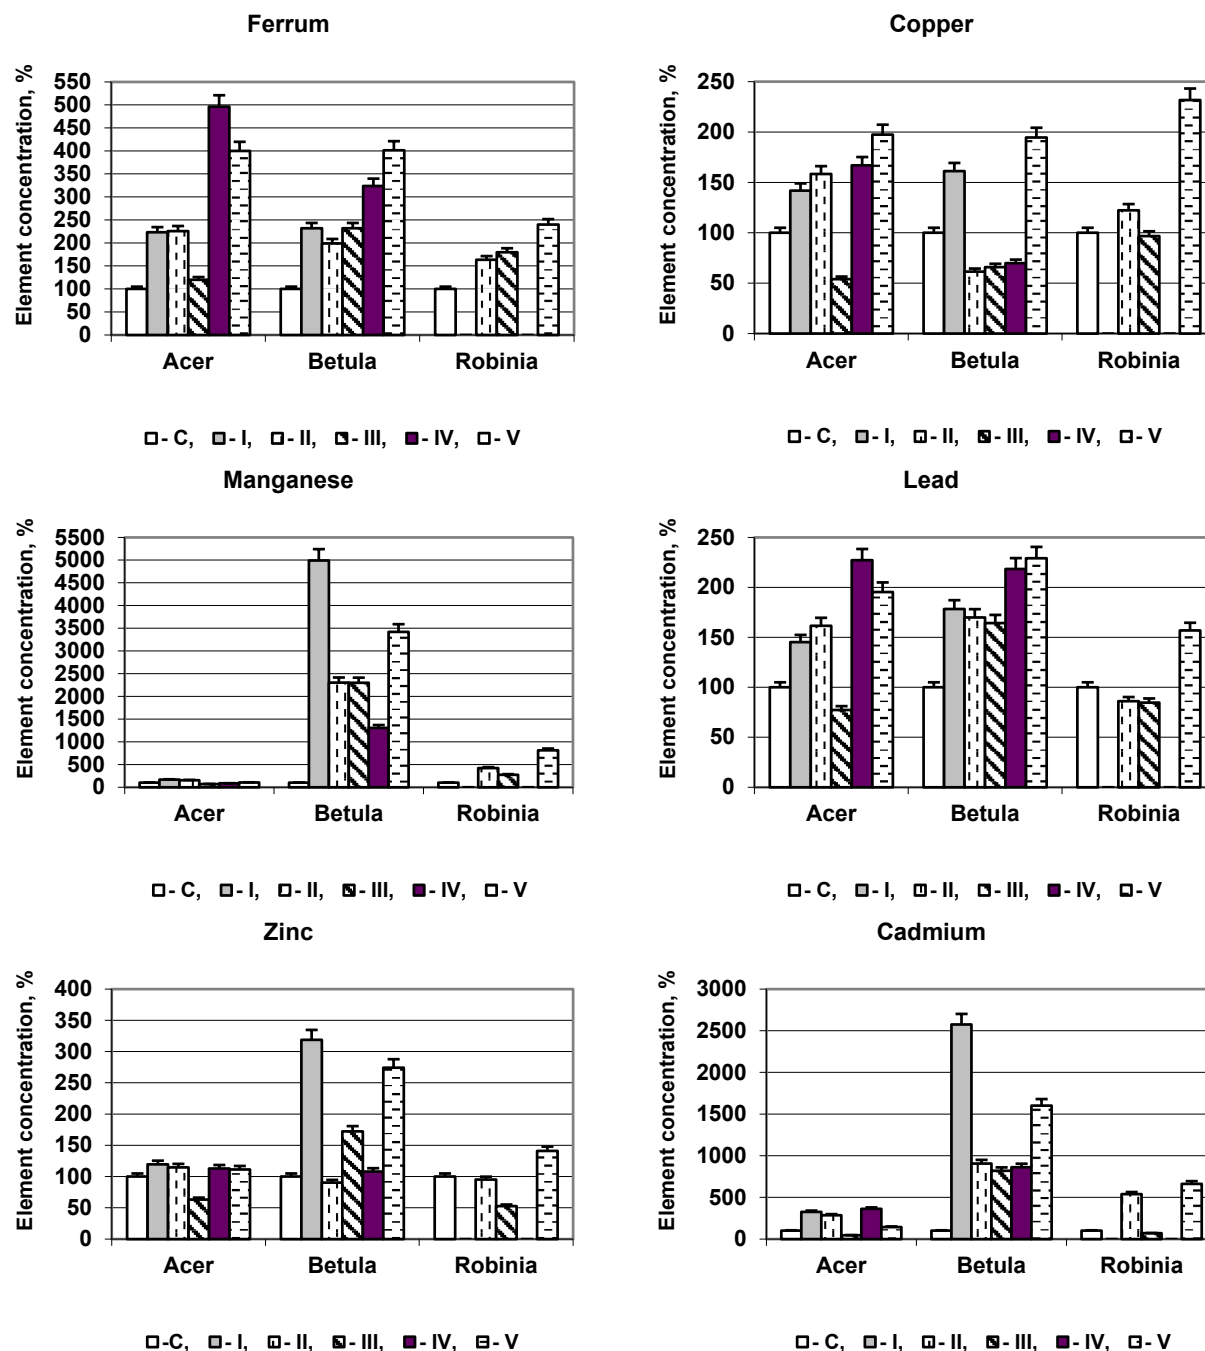

Fig. 4. The relative heavy metals content in the leaves of trees from the devastated lands at Kryvyi Rih district. The element content in the control is 100%. Research areas: C – control, I, II, III, IV, V plots on devastated land. Acer – Ash-leaved maple, Betula – Silver Birch, Robinia – Black locust.

It is established that only Copper accumulation was statistically significant in the leaves of Black locust. The concentration of this metal was by 1,2-2,3 times ($p < 0,05$) above the control values. In the leaves of other tree species both high and low Copper content were

detected. Thus, the concentrations of this metal exceed the control values: by 1,4-2,0 times ($p < 0,05$) at plots I, II, III and V in Maple, by 16,9 times ($p < 0,05$) at plots I and V in Birch. At the same time, the Copper content in the leaves was lower than the control values: by 46%

($p < 0,05$) at plots III in Maple, by 31-39% at plots III and IV in Birch.

Our findings (Fig. 4) show that Lead concentrations in Birch leaves at all the plots were higher than the control values by 1,6-2,3 times ($p < 0,05$). In Maple leaves at plots I, II, IV and V this metal's concentrations were also higher than control values, by 1,5-2,3 ($p < 0,05$). But at plot III the Lead content was below than control by 23% ($p < 0,05$).

In Black locust leaves, this metal accumulation was detected only at plot V, where its content was 1,6 times higher than control ($p < 0,05$). At the same time at plots III and IV, the Lead concentrations were below than control values by 14-16% ($p < 0,05$).

Cadmium content in the leaves of woody plants exceed the control values: by 9-25 times ($p < 0,05$) in Birch, by 5,4-6,6 times ($p < 0,05$) in Black locust and by 5,4-6,6 times ($p < 0,05$) in Maple. It should also be noted that at plots III, the concentration of this metal is below the control values in the leaves of Maple and Black locust a, respectively by 32% and 45% ($p < 0,05$).

4 Discussions

All macronutrients that we have studied (K, Ca, Mg, P, and S) are biologically significant chemical elements. Therefore, these elements have a significant influence on all the important processes of life, growth and development of woody plant species [5, 12, 15]. In the course of evolution, for each chemical element, a certain interval of optimum was formed. The information about this interval is very important for the biological evaluation of the element content [8, 9].

According to scientific publications, the optimal Potassium concentration in plants is from 10 000 to 14 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w., while the content of this element exceeding 25 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w. is considered as phytotoxic [6, 8, 9, 20]. According to the results of our research, at a control site in the leaves of Black locust and Birch, the Potassium concentration was below the biological optimum (4 200-4 700 $\text{mg}\cdot\text{kg}^{-1}$ d.w.). The content of this metal in the leaves of Ash-leaved maple was slightly higher (about 10 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w.), but it was at the lower level of biological optimum.

On devastated lands at Kryvyi Rih iron-ore & metallurgical district, the Potassium concentration ranges from 200 to 870 $\text{mg}\cdot\text{kg}^{-1}$ d.w., which is much less than the values of biological optimum. This is undoubtedly indicative of a deficiency of Potassium content for these plants.

The average optimal Calcium concentration in plants is between 10 000 and 20 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w., and its phytotoxic amount is over 40 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w. [6, 8, 9, 20]. At the control site, the concentration of this element was within the biological optimum. On devastated lands, the growth and development of woody plants occur with some deficiency of this macroelement. The Calcium concentration in Birch leaves is 6 400-11 300 $\text{mg}\cdot\text{kg}^{-1}$ d.w., in Black locust leaves is 7 800-16 400 $\text{mg}\cdot\text{kg}^{-1}$ d.w.

The average Magnesium concentration in plants actually coincides with the range of biological optimum

(1 000-3 200 $\text{mg}\cdot\text{kg}^{-1}$ d.w.), and the phytotoxic concentration is more than 5 500 $\text{mg}\cdot\text{kg}^{-1}$ d.w. [6, 8, 9, 20]. According to the results of our studies, the content of this metal in the leaves of trees at the control site is near the upper limit of the biological optimum (2 800-3 600 $\text{mg}\cdot\text{kg}^{-1}$ d.w.), but does not exceed the threshold of its phytotoxicity. On devastated lands, the Magnesium concentration in the leaves of trees in most cases was above the upper limit of the biological optimum (3 200 $\text{mg}\cdot\text{kg}^{-1}$ d.w.) but was below the phytotoxicity threshold (5 500 $\text{mg}\cdot\text{kg}^{-1}$ d.w.).

According to scientific publications, the optimal Phosphorus concentration in plants is 1 000-3 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w., the content of this element greater than 5,000 $\text{mg}\cdot\text{kg}^{-1}$ d.w. is considered as phytotoxic [6, 8, 9, 20]. We found that at the control site the Phosphorus, content in the leaves of trees was at the minimum level of its biological optimum 950-1 500 $\text{mg}\cdot\text{kg}^{-1}$ d.w. On devastated lands, in most cases, its concentration was much lower than the values of the biological optimum 350-750 $\text{mg}\cdot\text{kg}^{-1}$ d.w. This fact indicates a deficit of this macronutrient.

The range of biological optimum for Sulfur content in plants is 1 500-2 500 $\text{mg}\cdot\text{kg}^{-1}$ d.w. and the phytotoxicity threshold is greater than 5 000 $\text{mg}\cdot\text{kg}^{-1}$ d.w. and [6, 8, 9, 20]. We found that at a control site in the leaves of trees, the Sulfur content was below the values of the biological optimum (650-950 $\text{mg}\cdot\text{kg}^{-1}$ d.w.). On devastated lands, in all cases, the Sulfur concentration in the leaves of trees was higher than control. However, the content of this element, with rare exceptions (Black locust at plot II), was in the range of biological optimum and did not exceed the phytotoxicity threshold.

According to the scientific literature [3, 12, 13, 27], 100-250 $\text{mg}\cdot\text{kg}^{-1}$ d.w. Ferrum concentration in plants is considered optimal, and the phytotoxicity threshold is 500-550 $\text{mg}\cdot\text{kg}^{-1}$ d.w. We find that woody plants in all study areas contain extremely high concentrations of Ferrum in leaves: 300-500 $\text{mg}\cdot\text{kg}^{-1}$ d.w. at a control site and 650-2010 $\text{mg}\cdot\text{kg}^{-1}$ d.w. at devastated lands. Therefore, it can be assumed that woody plants are clearly exposed to the phototoxic effects of high concentrations of this metal.

Manganese content in plants from 50 to 200 $\text{mg}\cdot\text{kg}^{-1}$ d.w. considers as optimal, and if metal content is more than 300-400 $\text{mg}\cdot\text{kg}^{-1}$ d.w. a stable phytotoxic effect was observed [3, 10, 12, 29]. We found that at a control site a Manganese concentrations in the leaves of trees for all species was in the optimality range – 50-90 $\text{mg}\cdot\text{kg}^{-1}$ d.w. On devastated lands, the content of this metal in the Maple's leaves was slightly higher than the control values (70-170 $\text{mg}\cdot\text{kg}^{-1}$ d.w.), but does not go beyond the optimum. While, the Manganese concentrations in Black locust's leaves and in Birch's leaves significantly exceed the toxicity threshold (300-800 and 2300-5000 $\text{mg}\cdot\text{kg}^{-1}$ d.w., respectively). Hence, the plants are influenced by Manganese phytotoxicity.

For Zinc, the optimum range of its content in plants is 10-50 $\text{mg}\cdot\text{kg}^{-1}$ d.w. and its phytotoxicity threshold is 100 $\text{mg}\cdot\text{kg}^{-1}$ d.w. [10, 12, 26, 30]. According to our studies results, the concentrations of this metal in the leaves of Maple and Black locust were in the optimum range (both

at the control site and on the devastated lands (except for plot V)). In Birch leaves, Zinc concentrations reach 100-280 mg*kg⁻¹ d.w., which actually exceeds the phytotoxicity threshold.

Data from scientific publications indicate that Copper concentrations in plants of 5-10 mg*kg⁻¹ d.w. are maintained optimal, and the phytotoxic threshold is greater than 20 mg*kg⁻¹ d.w. [3, 11, 25, 26]. The results of our studies have shown that the concentrations of this metal in the leaves of all three tree species do not exceed the lower threshold of the optimum zone: at a control site – 1,4-2,4 mg*kg⁻¹ d.w. and at devastated lands – 0,8-4,6 mg*kg⁻¹ d.w. Therefore, we can assume that there is a deficiency of this important trace element.

The biological optimum range for Lead concentration in plants is 5-10 mg*kg⁻¹ d.w., and the phytotoxic threshold is 30 mg*kg⁻¹ d.w. [4, 11, 13, 20]. We have found that the content of this metal in the leaves of trees does not exceed the minimum value of the biological optimum: 0,13-0,21 mg*kg⁻¹ d.w. at the control site and 0,1-0,48 mg*kg⁻¹ d.w. at devastated lands.

According to scientific publications, the optimal Cadmium concentration in plants is 0,005-0,020 mg*kg⁻¹ d.w., the content of this element greater than 0,200 mg*kg⁻¹ d.w. is considered as phytotoxic [3, 10, 25, 28]. We found that at a control site, the content of this metal in the leaves of all three species was within the optimum range: 0,0029-0,0306 mg*kg⁻¹ d.w. At devastated lands, Cadmium concentration was also in the optimum range for Maple (0,0103-0,0234 mg*kg⁻¹ d.w.) and for Black locust (0,0029-0,0200 mg*kg⁻¹ d.w.). For Birch leaves, the content of this metal in all cases exceeds the values of the phytotoxicity threshold 0,2508-0,4897 mg*kg⁻¹ d.w.

Among the woody plants species that we have investigated, the maximum concentrations of macronutrients have been identified in Black locust and Ash-leaved maple. The maximum concentrations of heavy metals were found in the Silver birch.

5 Conclusions

Macronutrient (K, Ca, Mg, P, S) and heavy metals (Fe, Mn, Zn, Cu, Pb, Cd) contents in leaves of three tree species indicate a difficult ecological conditions on the Petrovsky waste rock dump devastated lands at the Kryvyi Rih iron-ore & metallurgical district. The growth and development of trees on these devastated lands is carried out with a clear nutrient's shortage (especially K and P) and metal's excess (especially Fe, Mn and Zn).

Taking into account the revealed values of macronutrients optimal concentrations and revealed the heavy metals lowest content in the leaves, we assume that Ash-leaved maple *Acer negundo* and Black locust *Robinia pseudoacacia* (compared to the Silver Birch *Betula pendula*) are more resistant to the geochemical conditions of devastated lands. Therefore, species of trees can be recommended for the creation of artificial tree plantations on devastated lands.

The authors are grateful to the DAAD program "Scientific Cooperation with Universities in Developing Countries" for the opportunity to perform analytical work at the Institute of

Biosciences Laboratory, Freiberg University of Technology and Mining Academy (Freiberg, Germany).

Geographical analysis of ecology-dependent diseases of Kryvyi Rih population in order to provide a sustainable development of the industrial regions

*Daria Shiyan**, *Iryna Ostapchuk*, and *Olena Lakomova*

Kryvyi Rih State Pedagogical University, 54 Gagarina Ave., Kryvyi Rih, 50086, Ukraine

Abstract. The geographical, ecological and territorial peculiarities of the dynamics and the appearance's reasons of the population's sick rate in dependence on the environment's state of Kryvyi Rih town with the aim of the stable development's provision of the industrial regions. The influence of the contamination's sources on the health state of the Kryvyi Rih population is cleared up and the space-time peculiarities of the sick rate's display are established: the influence of the environmental risks' factors on the population's sick rate and the display of the diseases' separate groups are defined, estimated and mapped, the spreading's indicators of the ecologically dependent pathology from the distance to the stationary sources of pollution and from the factors of the environmental risks are revealed. The statistical base is created and the factors' analysis of the environmental risks, the sick rate, the main demographical indicators of Kryvyi Rih population for the period of 2004 – 2019 is made and it's determined that the sick rate and the mortality, caused by it, play the essential role in the development of the demographical situation of Kryvyi Rih town.

1 Introduction

The peculiarities of the geographical research of the problem of the population's sick rate and its dependence on the display of the environmental risk in the limits of the definite territories are examined in the article. This problem is the geographical – spatial one, because the space-time run of the different types of diseases has the complex character, therefore it's investigated with the help of the geographical scientific methods. The geographical approaches permit also to reveal more efficiently (in comparison with the other sciences) the space-time independence between the appearance of the diseases and the specificity of the municipal environment. In particular, the process of spreading of the ecologically-dependent sick rate in the geographical space is described best of all by the model, according to which the ecologically-dependent diseases are spread from the centers of the environment's contamination, losing its activity from the center to the outlying area.

In contrast to the traditional medical-geographic zoning, the necessity to conduct the ecological-geopathogenesis zoning of the territories, on which the definite types of the population's diseases are developed, is proved. For example, the geo-spatial run of the population's sick rate in the industrial regions (Kryvyi Rih) and the separation of the regions with the different level of the environmental risk present the additional proofs, concerning the dependence of the internal-municipal spatial specificity of all the geographical processes and phenomena on the unique configuration and the specific geographical position of the town.

The problems of the population's sick rate interest the geographers for a long time. Such an interest is not accidental, because the geographic or the spatial specificity of these problems has always been so bright that it didn't remain any doubts, concerning the subject field of science, which has to solve them. However, if, except the medics [1, 2, 3], the representatives of the natural-geographic sciences were engaged in these problems, in particular, the bio-geographers [4, 5] not so long ago, then, the geographical [6-8] and the ecological approaches [9] become more and more actual lately in many publications. Due to this, the problems' studying process of the geographical peculiarities of the ecologically-dependent diseases' formation at the higher educational establishments gains the special actuality.

2 Literature review

Considering it necessary to research the theoretical-methodic turns of the ecologically-dependent diseases' problem, the authors made the analysis of the conducted theoretical and practical researches of the population's sick rate's problem and indicated the methodological landmarks strictly for the geographic sciences:

- the problem of the population's sick rate is almost not determined without the getting used to the space-time continuum. The first scientific researches in this direction didn't deal without the geographic maps [10];
- the spreading of the sick rates in the form of the epidemics, epizootics or epiphytes expresses the aspiration for the model "center-outlying area" [11],

* Corresponding author: shiyandv2017@gmail.com

generally known in the geographic sciences, and still further – the theory of the innovations’ diffusion of T. Hegerstrand [12, 13];

- the majority of the medical-geographic researches is connected with the natural centers of the diseases’ appearance and uses the landscape-scientific approaches [14];

- the medical-geographic researches of the ecologically-dependent diseases (changes of the arterial pressure, the disease of the respiratory organs’ systems, the urinary-sexual system and others) are more frequently connected with the anthropologic-genetic changes of the environment (the contamination of the atmospheric air by dust and chemical combinations, the radio-active contamination, the influence of the electromagnetic artificial fields and noise on health) [15, 16];

- the joint task of the Medicine and Geography is the search of the ways of the optimal interaction between the individual, economy and environment, both as the natural one and as the one, created by him (her) [17], the same tasks are solved by the conception of the stable development [18, 19];

- the single conception of the non-zero or the accepted risk dominates at the present time, because the risk’s level in any system cannot be equal to zero and it changes in the limits of the probability from 0 to 1, where 0 is the probability of the absolute inertness (the event does not happen in any case), 1 is the risk is realized (the event has happened) [20];

- there is no distinct definition of the notions social, ecological, medical risk, the risk of the human diseases’ appearance. There is the notion “environmental risk” [21] in the foreign publications as the risk for the human health in the result of changes of the environment’s quality; there is the notion “risk factors in health and disease” [22], in which the ecological factors, influencing the health state of the individual and the appearance of the diseases, act as the separate component. The authors will come out of the most widely-used notion “environmental risk” in the presented research, which acts as the inter-discipline and complex notion and permits to make the research of the ecologically-dependent diseases of the Kryvyi Rih population and to elaborate the measures on the provision and control of the risks’ high levels.

One general conclusion flows logically out of the points, mentioned above – the population’s sick rate appears in the background of the complex interaction of the person with the environment’s elements, where he (she) lives or works. And if the scientists were mostly interested in the natural components, being the objects of the investigation of the natural-geographic sciences [23-25], of this environment till the middle of XX century, then, the main priorities of the latest decades are presented mainly to the social and techno-genetic environment, which are already the objects of the geographic sciences [26, 27]. At this, the ecology joined the subject sphere of the medical-geographical problems which has more right for the research of the interrelations of the organism and the environment. However, such its direction as the ecology of an individual is recognized among the medics-geographers

as being “their own” [28, 29]. Afterwards, you may state that the problem of the population’s sick rate is also ecological.

The geographical peculiarities of the territories and their influence on the display of the population’s ecologically-dependent diseases play the significant role from the view point of the stable development’s conception. According to the results of the author’s researches, the modern social-economic and medical-geographical specificity of Kryvbas is much determined by the original territory’s stretching form of Kryvyi Rih town. But such form is the direct result of the spatial localization of the ore body, at the processing of which the settlement boundary was formed. Afterwards, the geological structure of Kryvyi Rih town forms that fundament, on which the further social-geographic, ecologically-medical processes are developing [30].

Unfortunately, the modern geographic researches are conducted mainly in the narrow scientific spheres and they don’t have the features of the complex and inter-discipline researches [28], but as far as the works, devoted to the “joint” directions, in particular, between the physical and the social geography, are concerned, – they are the single ones [22]. To our mind, the very such “joint” is formed during the last decade in the scientific approaches to the problem’s study of the population’s sick rate. The works of the geologists, the bio-geographers, the landscape scientists, the cartographers [29-32] appear still more and more frequently in the background of the great number of the investigations, conducted by the medics and presented mainly in the periodical publication “Environment and Health”. The interest of the geographers to this problem grows more and more [8]. The legitimacy of such approaches’ use is confirmed in the classical works on the diffusion of the innovations, where the spatial widening of the diseases is connected with the definite periods (stages) of the geographic space’s focusing [13].

The foreign researchers also pay an attention to the problem’s inter-discipline character of the appearance of the ecologically-dependent diseases and the environmental risk, among their number they separate such risk’s factors: the behavioral, physiological, demographic, ecological, genetic ones [22], speak on the necessity to unite the efforts of geography, psychology, sociology, law, economics, the public policy in the researches of the social risks [33]. Thus, in our opinion, the very such multi-factuality and the inter-discipline should become the leading characteristic feature, positing the problem of the geographic research of the population’s ecologically-caused diseases.

It’s difficult to research such a complex scientific problem from the position of one science, which would take into account, if possibly, all the components of the system “nature-population-economy”: climate, the geo-chemical background, the vegetable and animal world, the danger’s degree of natural disasters, the level of the economic development, the social-political order [34]. Correspondingly, the necessity appears to use the ways, methods and modes of the tasks’ solution in physical geography, geology, geo-physics and other natural sciences. Each of them, in its turn, absorbs the

knowledge's elements of the overlapping sciences, due to which gains the new results, necessary to reveal the regularities of the interaction of the nature and the society.

Such a complex approach to the problem's study of the people's sick rate started to develop actively on the land of the USA, beginning from 1980, when the ecological strategy of the state included the state management of the nature-use and the market mechanisms of its regulation. The very conception of the environmental risk has become the basis of the state ecological policy of the USA, according to the definition of the National Academy of Sciences of the USA, the estimation of the risk – is the use of the available scientific information and the scientifically-grounded forecasts for the arrangement of the influence's security of the harmful conditions and materials on human health [35]. At the same time, in the middle of the 80-s of XX century, the researches of the natural risks started to be held under the leadership of the professor S. M. Myahkov at the geographic faculty of MSU (Russia), he founded the bases of the new scientific direction – “Geography of Natural Dangers and Risk” [36].

At this, the “way out” to the practical solution of the problem in the research of the notion “environmental risk” is considered by the authors to become still more important. The risk's notion in the presented case is complex and it includes: the estimation of the ecological intention's sharpness of the definite geographical region, the level of the population's sick rate, dependence of the incidence of the population on the environmental situation and others.

It's hard to speak of the problem's research of the ecologically-dependent diseases without their relation to their spatial display and the determination of the space-time causes by the factors of the environment. The formation of the complex component's and the medical-geographical maps effects sufficiently the formation of the theoretical-methodological bases and the methodic ways in the medical-geographic researches, increases their meaning in the management's affair of the development and the territorial organization of health protection [37, 38].

The application's possibilities of GIS technologies at mapping of the ecologically-dependent diseases and the separation of the medical-geographical regions are important, their reflection on the map – is the result of the medical-geographic zoning, which reflects the objectively existing territorial dynamic systems, being similar enough on conditions of the social health formation [39].

The special relations in the middle of the medical-geographical regions are formed between the inhabited localities and the landscapes, surrounding them: the definite resources are withdrawn out of the nature, but the different wastes, which can be involved into the natural cycles of the circulation and create the unfavorable conditions for the population's health, enter the natural complexes.

The number and the sizes of the inhabited localities increase with the development of the territory.

Sometimes the run of the processes acquires the reverse character in so-called the depressive regions – the number of the population becomes less; the agricultural fields are overgrown and others. The analysis of all the changes, happening in the structure of the medical-geographical regions, permits to reveal the main regularities of their development and to create the medical-geographic forecasts on this basis [39].

The researches of the ecological problems have become more intensive for the last years, the medical geography began to develop qualitatively new approaches and methods for studying the incidence of the population. Therefore, the thought begins to widen among the geographers that the sick rate of the population may be considered to be the most sensitive indicator, characterizing the environment's influence on the person and vice versa [40, 41].

Properly, paying the attention to these new approaches, the authors formed the idea of the ecologically-dependent diseases [42], being confirmed in the other modern works too [16, 21, 43]. Thus, according to the opinion of O. P. Gavrylenko [40], there are such indicators among the negative indicators of ill-health, the spreading of which depends, to a certain extent, on the state of the environment. These diseases are called the ecologically-dependent [40]. The environment can also have the characteristic features, being strictly not pathogenic for the person, but during the interaction with them the potential danger for the person to have the disease grows. We call such an effect as being multiplicative, caused by the phenomenon of synergism, in our works [20, 42]. This is the thing that causes the actuality of our research.

Basing on the analysis of the previously conducted researches in the sphere of the ecologically-caused diseases and the influence of the ecological factors on their appearance, the conducted researches of different types of risks, the grounded theoretical-methodological bases of the indicated problem, the authors investigated the geographical and ecological peculiarities of the dynamics and the reasons of appearance of the population's sick rate in dependence of the environment's state of Kryvyi Rih town. The analysis of the sick rate for the separate diseases on the territory of Kryvyi Rih, as the industrial town, is made with the help of the specialized data base in the environment GIS MapInfo Professional. The territorial peculiarities of the population's sick rate of the industrial region are researched in the work, the classification of the Kryvyi Rih regions, according to the population's sick rate, is made, the ecological-geo-pathogenic zoning of the Kryvyi Rih territories is grounded and made on the basis of the investigation of the internal-regional peculiarities of the population's sick rate. The research results are introduced by the authors into the training process of the Geographic faculty's students and are included into the lecture-practical studies on the disciplines “Geo-Ecology”, “Bases of Geo-Ecology”, “Ecology and Ecological Tourism”.

The influence of the contamination's sources on the population's health state of Kryvyi Rih town is cleared up and the space-time peculiarities of the sick rate's

display are established (the influence of the environmental risks' factors on the population's sick rate is defined, estimated and mapped). The research is conducted at the Department of Physical Geography, Regional Ethnography and Tourism on the basis of the Kryvyi Rih State Pedagogical University by the collection and the statistical analysis of the factors' data of the environmental risks, the sick rate, the indicators of the birth-rate, mortality and natural increase of the Kryvyi Rih population in the period of 2004–2019. The factors of the environmental risks are estimated, the stable dependence of the ecologically-caused diseases on the pollution of the atmospheric air, the surface waters, the grounds is revealed, the statistical analysis of the population's sick rate is made and the ecologically-dependent diseases are mapped, the dependence's indicators of the ecologically- dependent pathology's spreading from the distant area to the stationary sources of contamination and on the factors of the environmental risks are revealed.

It's determined, that the very complex geographic researches of the population's sick rate acquire more and more importance on conditions of the stable development's provision of the industrial cities, because their display and results have the double character: from one side, they are caused by the ecological situation of the region and are the display's result of the ecological factors of different genesis (the pollution of the atmosphere, the surface waters, grounds and others), from the other side, – they are the expression of the separate type of the environmental risks.

The geographical approach to the state's study of the population's sick rate for the ecologically-caused diseases of the industrial region, in dependence on the complex of the landscape, social-economic and ecological characteristic features of the separate territories, is improved.

3 Methods

The research is conducted with the use of the general-scientific ways and methods: the statistical-mathematical (for the estimation of the quantitative parameters of the population's sick rate with the ecologically-dependent diseases, the estimation of the ecological situation of Kryvyi Rih town and the contaminations from the stationary and movable sources, the estimation of the environmental risks' factors); the mathematical (for the calculation of the spreading's dependence indicators of the ecologically-dependent pathology from the distant area to the stationary sources of pollution); the system-structural and the system-functional analysis (the research of the complex connections in the system "nature-population-economy", appearing in the development's process of the ecologically-dependent diseases in the industrial regions). The special ways and methods are used: the comparative-geographical analysis (the study of the territorial distinctions of spreading of the ecologically-dependent diseases, the dependence's determination of the ecologically-dependent diseases on the factors of the environmental risks); the historical-

geographical analysis (the research of the space-time regularities of the display of the environmental risks and the ecologically-dependent diseases, the dynamics of the ecological situation, the sick rate, the birth-rate, mortality and the natural increase); the cartographical one (the realization of the territorial differentiation and the spatial analysis of the sick rate's appearance and spreading and the determination of the sick rate's dependence on the display of the environmental risks' factors in the limits of the definite territories, the realization of the medical-geographic zoning); the probability one (the methods of the factors' estimation of the environmental risks on the basis of the probability of the landscape's refusal to fulfill the set functions), elaborated by M. D. Grodzynsky [44, 45]: 1 – the estimation's methods of indicators, according to the frequency of the events (refusals, restorations, the transition between the states' spheres), 2 – the methods of estimation, according to the function of the incidental values' distribution (time of the refusal's appearance or the restoration of the landscape), 3 – methods of estimation, according to the variation of the indicators in the limits of the set range.

4 Results

The territory of Kryvyi Rih belongs to the steppe landscape's zone. It's determined by the research on the basis of the functional analysis of the town that the industrial zone consists mainly of over 100 enterprises of the mining-extractive (mines, carriers, the area is 33 sq.km), processing and metallurgical branches (5 mining-dressing combines, the metallurgical combine "ArcelorMittal Kryvyi Rih", a series of the machine-building and processing plants); the residential area – is represented by the low-building's and tall-building's residential areas, the cottage settlements; the agricultural one – by the arable lands of different specialization, the pasture-grounds and the garden landscapes; the water farming – by the rivers, storage reservoirs, the irrigating and arterial canals, lakes; the travelling-transport one – by the railways and automobile roads of different categories, the garage and station complexes; the environment-creating one – by the forestry complexes, parks, squares and the objects of the natural-protected land fund (the landscape areas of the general-state meaning – the "Ingulets steppe" and the "Balka Pivnichna Chervona"); the zone of the marching complexes is represented by the various destructive landscapes and the waste grounds.

The industrial, residential and agricultural landscapes dominate in the territorial structure of the town. The difficult interaction of nature and economy leads to the formation of the different anthropogenic and anthropogenically modified landscapes, but putting of the anthropogenic processes over the natural ones leads to the formation of the ecological situations and creates the pre-conditions for the active display of various types of the environmental risk, the estimation's results of which are presented lower.

The risk's estimation of the atmospheric air pollution showed that nearly 90 % landscapes of Kryvyi Rih are characterized by the levels of probability of occurrence 0,7–1, including the residential, environment-creating, water farming zones and the suburban complexes; 10 % – by the probability level of 0,2–0,7. The hydro-geological risks have the very high probability of occurrence (it's displayed in all the water landscapes of the town and was equal to 0,7–1). The probabilities among the hydro-geological risks were estimated in such a way: the indicator of the contamination of the underground waters varies in the limits of 0,2–1, however, 85 % of the territory are estimated by the high probability (0,4–0,7); nearly 6 % – by the very high one (0,7–1); 9 % – are coincided with the exploitation of the deposit – not estimated; the probability of the flooding varies from 0 to 1 and displayed only on 30 % of the territory, occupied by the different hydro technical structures; the risk of the appearance of floating sands and change of big rivers and silting of rivers is presented locally (they are estimated qualitatively as they were spread on the very limited territory of the region). The geological-geo-morphological risks are estimated, according to the four types: the risk of the gravitational processes is represented by the landslides (0,03–0,18) and crumbles (it's revealed on the sides of dumps and carriers, the probability – 1); the risk probability of the formation of fissures and cracks of the land surface above the mine excavations equals 0,02–0,75, but the risk probability of crashes – 0,013–0,25.

The risk of activation of the karst-suffosium processes is estimated by the average and not high meanings of the probabilities (0,2–0,5), it affects the functioning of some types of the landscapes – the residential, agricultural and park ones. The risk of the activation of the tectonic processes is important (0,5–0,75), according to the possible results of its display.

The ground risks are estimated by 4 types: the risk of the grounds' contamination by the chemical substances has the extreme and very high probability (0,7–1) per 50 % of the town area; the risk of the grounds' water logging – not high, but for the separate kinds of the landscapes (especially for the suffosium and the water-dividing valleys, raving and sloping ones) – essential; the risk of the grounds' salting is lighted up by the not high levels of the probability and has the territorial connection with the risks of the water logging and flooding; the risk of the acidity level's change of the grounds is developed in the same types of the landscapes as the two previous ones and has mainly the low levels of the probability's display, except the landscapes of the suffosium valleys [20].

The risk of display of the exotic-genetic geological processes is estimated for 30–45 % of the landscapes' types as the high one (used intensively by the person).

The integral indicator's estimation of the environmental risk probability showed that it is formed on the territory of Kryvyi Rih by 17 types of the risks, being estimated above, but not all of them have the urgent importance in the creation of this indicator's high probability, therefore the analysis was made on the basis of the selection of those types of the landscapes, where

the equal probabilities of the separate types of risk were above 0,7. It's stated that the number of risks with the high level of probability ($\geq 0,7$), those ones that urgently cause the high integral indicator, lie in the limits 1–5. The map is made, according to the results of the conducted estimation and on the basis of the component analysis of the risk. The analysis showed that nearly 65 % of the territory experienced the one- and the two-components risk, the significant role here was played by the risk of pollution of the atmospheric air, the surface and the underground waters, the rest one – 35% – experienced the risk, according to the 3, 4, and 5 types of the environmental risk. All the residential tall buildings' and some low buildings', the industrial and destructive, some agricultural and the environment-creating types of the landscapes have the high level of the multi-components' environmental risk. 11 electronic maps of the environmental risks were made for Kryvyi Rih, according to the estimation's results, with the help of the GIS-technologies and Corel draw.

It's determined that the biggest influence on the appearance of the ecologically-dependent diseases is made mainly by the pollution of the atmospheric air, the surface and underground waters, the contamination of the grounds; the special role is played by the probability of the untimely death of the population, due to the various socio-techno-genetic factors, but you shouldn't ignore such a fact that all the complex of the investigated factors of the environmental risk affect the population's state of health and sick rate, because they are in the whole forming the environment's quality of human life and are closely connected with each other.

The authors understand the environmental risk as the probability of the disease's appearance of the person, living or working in the limits of the definite landscapes. The estimation of the environmental risks is made by the authors on the basis of the comparative research of 17 types of risks (the environmental risks, described above) and the indicators of Kryvyi Rih population's sick rate for the period of 2004–2019, and also on the basis of the statistical models' construction of spatial distribution of the effects of environmental pollution on the population's sick rate, dealing with the ecologically-dependent diseases.

The gained data of the environmental risks' estimation testify that the highest indicators of the general sick rate of the population are characteristic for such regions of the town as the Pokrovsky, Saksagansky, the Central-Municipal ones, on the territory of which nearly 50 industrial enterprises are situated, they are mainly the acting mines, carriers and the dumps of the mining-ore-dressing combines and the combines themselves, the full-cycle metallurgical combine "ArcelorMittal Kryvyi Rih". The comparison of the data of the population's general sick rate with the maps of the risk of the town's atmospheric air pollution shows that the territory of the Saksagansky and the Central-Municipal regions coincides with the territory of the mostly polluted air. The lowest indicators of the population's general sick rate are characteristic for the Ternivsky and Inguletsky regions (these are the most northern and the most southern regions of the town), and

if the air pollution's indicators are not high in the Ternivsky region (1–5 of LAC, -the Limiting Admissible Concentration), then, the territory of the Inguletsky region is characterized by the high enough indicators of the pollution (5–15 of LAC). Such situation is explained by the fact that the data of the population's sick rate are collected at the separate remedial-preventive establishments, besides, the balance-wheel migrations of the population also play their roles in the middle of the town and the individual indicators of health (the influence of the genetic, social, moral and other factors).

The analysis of the population's sick rate of Kryvyi Rih for the researching period, according to the groups of diseases, shows that the greatest number of the sick rates of both among the adult population and the children's one is referred to the group of the blood-circulation diseases (point 8 on the graph: Fig. 1, 2) and the diseases of the respiratory organs (point 10 on the graph: Fig. 1, 2), the urinary-sexual system's diseases play a bit less role (point 15 on the graph: Fig. 1, 2) and other diseases (Fig. 1, 2)

Fig. 1. The sick rate of Kryvyi Rih population for 2004.

Fig. 2. The sick rate of Kryvyi Rih population for 2019.

The conventional symbols: 1 – some infectious and parasitical diseases, 2 – neoplasms, 3 – diseases of blood, the blood-creating organs, 4 – diseases of endocrine systems, 5 – diseases of nervous system, 6 – eye diseases, 7 – ear diseases, 8 – diseases of blood circulation system, 9 – heart diseases, 10 – diseases of respiratory organs, 11 – diseases of digestion organs, 12 – liver diseases, 13 – skin diseases, 14 – diseases of osseous and muscular system, 15 – diseases of urinary and sexual system, 16 – diseases of milk gland. The total number of diseases at the hospitals is indicated on the graph by the lines.

The research of the spatial distribution's influence of the contamination's sources on the population's sick rate and the gained data of the environmental risk's estimation was conducted, according to the methods of the statistical modelling (the regressive analysis) and with the help of GIS MapInfo Professional. A series of maps of the population's sick rate of Kryvyi Rih town, dealing with the different groups of diseases, was

constructed by the authors on the basis of the conducted analysis; the maps of the sick rates with the system's diseases of the blood circulation and the respiratory organs are presented on the figures 3, 4. The constructed maps and the estimated environmental risks visualize and confirm the dependence between the contamination and the sick rate of the population, characterize the sick rate of the population, dealing with the separate diseases.

Fig 3. Circulatory system's morbidity data 2019.

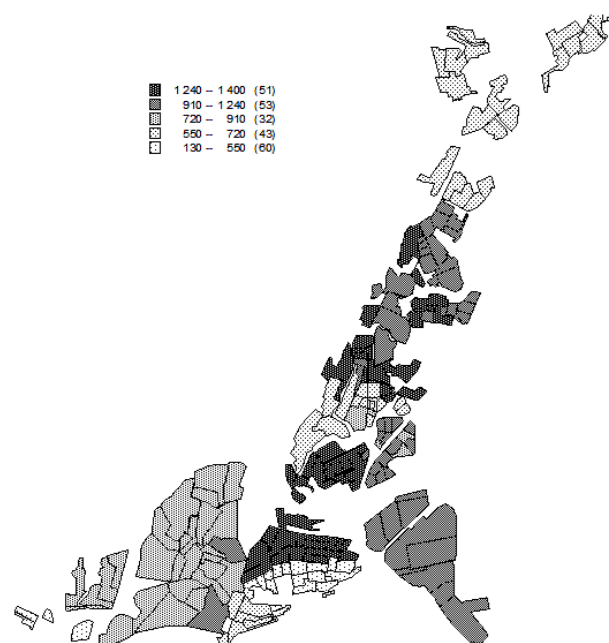

Fig 4. Respiratory system's morbidity data 2019.

In order to construct the regressive models, the authors fulfilled the non-linear analysis for the main groups of the ecologically-dependent diseases for the period of 2004–2019. It's cleared up, that the biggest determination from the quality of the atmospheric air is observed for the diseases of the blood circulation system (the coefficient of the determination is 0,43–0,49), the

diseases of the respiratory organs (the coefficient of the determination is 0,3–0,5).

Some graphics of the regressive disease's dependence of the blood circulation system and the respiratory organs on the distance to stationary sources of pollution in 2004, 2019 are presented lower (Fig. 5, 6, 7, 8).

Fig. 5. Regressive model of blood-circulation's disease dependence on distance to stationary sources of pollution (2004).

Fig. 6. Regressive model of blood-circulation's disease dependence on distance to stationary sources of pollution (2019).

Fig. 7. Regressive model of respiratory organs' disease dependence on distance to stationary sources of pollution (2004).

Fig. 8. Regressive model of respiratory organs' disease dependence on distance to stationary sources of pollution (2019).

The analysis of the constructed regressive models (Fig. 5-8) proves that the dependence of the sick rate with the definite groups of diseases on the ecological factors, in particular, the state of the atmosphere, is important. In most cases it is described exactly enough by the polynomial of the second degree with the meaningful coefficients of the determination. The regressive models, presented above, represent the

dependence of the population's sick rate on the state of the air basin in the generalized form. The conditional dependence's stability of the definite diseases on the environment's conditions is also confirmed by the statistical analysis on the construction's basis of the model of the spatial distribution of the contamination's influence on the population's sick rate.

Taking into account the results of the investigations and the results of the expert estimations [46, 47], the grouping of the diseases, according to the degree of the different factors' influence on the process of their appearance, was made and the stable interconnection and the dependence of the disease's display on the environment's state of human life is determined (Table 1).

Table 1. Distribution of separate components into creation of ecologically-dependent diseases.

	Diseases	Contribution of separate components			
		ecological	social	genotype	industrial
1	Some infectious and parasitical diseases	++	+++	++	+
2	Neoplasms	+++	—	++	++
3	Diseases of blood, blood-creating organs	++	+	+++	+
4	Diseases of endocrine system	+++	++	++	+
5	Diseases of nervous system	—	++	+	+
6	Diseases of eye and adventive system	++	+	++	++
7	Diseases of ear and comforter-type appendix	—	+	+	++
8	Diseases of blood circulation system	++	+	++	++
9	Heart diseases	++	++	++	+++
10	Diseases of respiratory organs	+++	++	++	+++
11	Diseases of digestion organs	+++	+++	++	+++
12	Liver diseases	++	++	++	+
13	Diseases of skin and hypodermic cellulose	+++	++	+	++
14	Diseases of osseous-muscular system	+++	++	++	++
15	Diseases of urinary-sexual system	+++	+	+	++
16	diseases of milk Gland	+++	++	+	+

The peculiarities of the environmental risks' display, the character of the population's sick rate distribution, the display of the most number of the diseases of the separate groups (blood circulation system and respiratory organs), determined by the authors, may influence the indicators of the birth-rate, mortality and the natural increase of population.

The distribution of the dead people's quantity for the separate reasons of death throughout Kryvyi Rih town

(Fig. 9) shows that the first place is occupied by the diseases of the blood circulation system (67 %), the second one – the oncological diseases (12 %), the third one – the diseases of the respiratory organs (3 %) and other diseases.

The number of Kryvyi Rih population was reducing during the research period (2004–2019). It was caused by the small number of the new-born children, not exceeding the number of the dead people, and the negative balance of the migration from 2007. The population is getting old, due to the growth of the average duration of life and the small quantity of the new-born children. The part of the young people reduces, but the part of the elderly people grows. From 2004 to 2019, the coefficients of the birth-rate (the average number of children, born by the average-statistical woman during the life) grew constantly: from the indicator of 0,97 of a child for a woman in 2004 till 1,32 of a child for a woman in 2019, the summary

coefficient of the birth-rate doesn't achieve the level of the natural replacement, being equal to 2,1 – it means that the number of the town population will be less, if the migration balance is left negative.

The number of the population reduced, first of all, due to the constantly high coefficient of mortality among the elderly people. Besides, the small quantity of the new-born children and the flow of the population back didn't give any opportunity to compensate the indicator of mortality. The migration's flow of the population back, which started in 2007, was caused by the optimization of the personnel's number at the powerful enterprises of the town, especially by the introduction of the programs, concerning the personnel's dismissal, according to their own wish, from the PJSS "ArcelorMittal Kryvyi Rih". At the same time, the tendency, concerning the reduction of the migration's upsurge of the population, was observed.

Fig. 9. Distribution of dead people's quantity in time cuts for separate reasons of death.

5 Conclusions

The scientific results of the research have the special methodical and practical value for the realization of the similar scientific investigations in the other industrial regions.

The conducted analysis and estimations are the methodic and practical basis for the realization of the Kryvyi Rih strategic development, particularly, in the parts of the territorial planning of the town, the organization of health protection, the ecological monitoring of the territory, the statistical data base and others. The cartographical, ecological, medical data, being gained in the research, are used by the statistical department of Kryvyi Rih town, the department of health protection of the municipal executive committee of Kryvyi Rih, the ecological department, the ecological inspection, the department of architecture and planning and also the Institute of the town's development.

The complex of the events [20], being oriented at the minimization of the environmental risks, being realized via the landscape- and territorial-planning, the environment-creating events, are elaborated. The

research results are taken into account in the project of creation of the Kryvbas ecological net, the organization of the sanitary-protective and water-safeguarding zones of the rivers and water reservoirs, the buffer zones of the nature-protection objects, the suburban zones of the town.

The results and the regularities of the formation of the ecologically-dependent diseases, the medical-geographic zoning of Kryvyi Rih territory may serve as the ecological criterion of the environment's quality of human life and be correspondingly used by the local population for the selection of the place of the residential premises' location in the limits of Kryvyi Rih town. Besides, the knowledge of the ecological situation of the definite region may be one of the criteria of the formation of the cost and price of the residential premises (rent or purchase) and the basis for the creation of the so-called "ecological rent".

The expressed positions of the article are used in the scientific and training processes at teaching of the disciplines of the ecological, geographical and cartographical direction at the Kryvyi Rih State Pedagogical University.

Thus, the research, conducted by the authors, is directed at the provision of the stable development of Kryvyi Rih, in which there are:

- 1) the rational and complex use of natural conditions and resources of the Kryvyi Rih basin of iron ores;
- 2) the healthy qualified environment of population life;
- 3) the influence's minimization on natural components (requires the diligent research in the perspective).

The geographic research of the ecologically-dependent diseases of Kryvyi Rih population showed that the display and the consequences of such sick rates have the double character: from one side, they are caused by the ecological situation of the region and are the display's result of the ecological factors of different genesis (the pollution of the atmosphere, the surface waters, grounds and others), from the other side, they are the expression of the environmental risks of separate type and in such case it's the probability of the disease's appearance for the person, living in the limits of the definite town.

The conducted analytical, statistical, graphical and the cartographical researches confirmed the position on the fact that the original environment of the population life is being formed in Kryvyi Rih town (with its specific configuration, socio-economic peculiarities, economic specialization in the spheres of the extractive and processing industry). The display's peculiarities of the separate types of the environmental risks, which appeared to be high and extremely high in the limits of the researched town, are determined by the authors. It's cleared up that all the residential tall buildings and some low buildings, the industrial and destructive, some agricultural and environment-creating types of the landscapes have the high level of the multi-component's environmental risk, – thus, the town territory is characterized by the extremely low environment's quality of human life.

The formation's peculiarities of the ecologically-dependent diseases and their space-time dependences are determined. Such comparisons of the space-time regularities of the display of the environmental risks and indicators of the population's sick rate showed that the maximal risk to get the disease is characteristic for the people, who live in the limits of the terrace tall landscapes (0,90), and a little bit less – in the limits of the flood-landed, low, the terrace low, the erosive-ravine and powerful tall and low buildings, near the water-dividing valley tall buildings' landscapes (0,71–0,78), the lowest probability of risk is defined for the water-dividing valley low buildings' types of the landscapes (0,54). The analysis of the population's sick rate, according to the group of diseases, showed that the greatest number of the population's sick rate both among the adult population and among the children's population is referred to the group of the diseases of the blood circulation system, the respiratory organs, the other diseases play a bit less role. These data are confirmed by the constructed statistical regressive models – the dependence of the sick rate with the definite groups of diseases on the ecological factors is revealed, in particular, the atmosphere state, the regressive dependence of the sick rate of the blood circulation

system and the respiratory organs on the distance to the stationary sources of pollution.

It's stated on the basis of the analysis of the main demographic indicators and the indicators of the population's sick rate of Kryvyi Rih that the sick rate and the mortality, caused by it, play the essential role in the development of the demographic situation.

Thus, the authors confirmed the supposition on the fact that the display of the ecologically-dependent diseases in the industrial towns is constantly connected, in the first turn, with the high levels of the pollution's probability of the atmospheric air, the surface and underground waters, grounds; the indicators' dependence of the birth-rate, mortality and the natural increase of the town's population on the high level of the probability of the environmental risk's display is cleared up.

It's determined that the very complex geographic researches of the population's sick rate acquire more and more importance on conditions of the stable development's provision of the industrial cities and towns.

Visual test determination of trace amounts of germanium in the form of an ionic associate of 12-molybdo germanate with astrafoxin

Tetiana Selivanova^{1,*}, Andrey Vishnikin², and Lyudmila Tsiganok²

¹Kryvyi Rih State Pedagogical University, Kryvyi Rih, Ukraine

²Oles Honchar Dnipro National University, Dnipro, Ukraine

Abstract. Sorption-colorimetric and naked eye determination of germanium as ion associates of $\text{GeMo}_{12}\text{O}_{40}^{4-}$ with triphenylmethane dyes is described. The sorption of the ionic associates (IA) of 12-molybdo germanate with astrafoxin (AF) on filter paper was studied. The colored scales for naked eye detection and dependence of chromaticity coordinates from the germanium (IV) concentration were obtained. The methods were applied to the determination of germanium (IV) in coked coal, iron ore, and in waters in the concentration range from $4 \cdot 10^{-8}$ to $1 \cdot 10^{-6}$ mol·L⁻¹. The developed test-systems for the determination of Germanium in natural and technological objects were tested in the course of training students of chemistry of Kryvyi Rih State Pedagogical University.

Introduction

Control of the content of germanium is necessary when it is extracted from ores, concentrates, coal, in its production, in cosmetics and medicines, in food. Plants that are capable of absorbing germanium and its compounds from the soil include: ginseng, garlic, camphor, aloe, tomatoes, beans, chickpeas, sunflower seeds, mushrooms and wheat bran. Germanium is also found in milk and in salmon meat. Germanium is an important trace element for humans, capable of accumulation. But its excess in the body or lack leads to the formation of various diseases. Germanium deficiency can be dangerous, since in this case the risk of the onset and development of cancer, as well as osteoporosis, is increased.

Today it is necessary to have reliable, simple and relatively fast methods for its determination. The main methods for the determination of germanium (IV) today: atomic absorption method with electro-thermal atomization of the sample (AAS-ETA) [1, 2], with mandatory preliminary concentration, atomic emission spectroscopy with inductively coupled plasma (AES-ICP) [4], voltamperimetric determination of germanium. Highly selective methods of atomic absorption analysis with electrothermal atomization or hydride version have their drawbacks. First of all, matrix elements interfere strongly with the determination, and the separation process only complicates and increases the analysis time. X-ray spectral and neutron activation methods to achieve sensitive, $\text{Sn} = 10^{-3}$ µg. But as for Germanium there is the problem of the formation of refractory carbides, introduced impurities from reagents, and other

factors that interfere with the determination using physical methods of determination.

A significant part of the existing methods for determining germanium (IV) are spectrophotometric, with mandatory separation procedures. The main methods of separation are distillation or extraction of germanium chloride in a strongly acidic medium in the form of a complex with phenylfluorone or other reagents. But these methods also have their drawbacks - the slow formation of a complex with phenylfluorone.

Therefore, it is relevant to develop highly sensitive, express methods for the determination of low contents of germanium (IV) and the creation of test methods for its semiquantitative determination.

To enhance the analytical signal in modern analysis, began to use the inclusion of chromophore groups with a high molar absorption coefficient in the analytical form. Until this time, triphenylmethane dyes, antipyrine and rhodamine dyes were most widely used (Table 1). The pH range in which these dyes exist in a cationic form is narrow. Recently, polymethine series dyes with a high molar absorption coefficient and a sufficiently wide pH range for the existence of singly charged cations have attracted their attention.

With these dyes, ionic associates (IA) of heteropolyanions (HPA) form solutions or pseudocolloidal solutions that allow the determination of heteroatom elements at a concentration level of 10^{-8} – 10^{-7} mol/L [3, 6].

Currently, there are not enough test methods for determining germanium.

This work is devoted to studying the conditions of selective sorption of the ionic associate (IA) of the molybdo germanium heteropolyanion (GPA) with the

representative of polymethine dyes – astrafoxin (AF) on cellulose paper (Table 1).

Reagents and equipment

All solutions were prepared using bidistilled water and stored in plastic containers. To obtain the IA of the molybdo germanium complex (MGK), the following was used: the initial 0.01 M solution of germanium (IV) was prepared by dissolving the corresponding portion of the GeO_2 grade of os.h. with a solution pH of 11.5; 0.1 M solution Na_2MoO_4 – from the recrystallized $\text{Na}_2\text{MoO}_4 \times 2\text{H}_2\text{O}$ grade of the chemical grade product recrystallized from a water-alcohol medium; $1 \cdot 10^{-3}$ M solution of astrafoxine was prepared from the preparation of the analytical grade mark $\text{C}_{25}\text{H}_{29}\text{N}_2\text{Cl}$ (Basic Red 12, 1,3,3-trimethyl-2- [3- (1,3,3-trimethyl-2-indolinylidene) propenyl] – 3H-indolium chloride). Solutions of a lower concentration were obtained by

diluting the stock solutions. For dynamic sorption on filter paper, a column was used (Fig. 1):

Fig. 1. Column for dynamic sorption on filter paper: 1 – a funnel with thread (2) and a plate for filter paper; 3 – glass connecting tube; 4 – rubber stopper; 5 – flask with a tube for filtering under vacuum.

Table 1. Photometric determination of Germanium in the form of IA with HPA with organic dyes.

Element	Analytical form	Colorant	λ , nm	ϵ , $\text{l} \cdot \text{mole}^{-1} \cdot \text{cm}^{-1}$	detection limit, mg/l	Source
Germanium	$\text{GeMo}_{12}\text{O}_{40}^{4-}$	Crystalline violet	590	$1,8 \cdot 10^{-5}$	0,025 – 0,3	[1, 3]
		Malachite green	620	$1,6 \cdot 10^{-5}$	0,030 – 0,4	[6, 3]
		Brilliant green	620	$1,93 \cdot 10^{-5}$	0,025 – 0,35	[1, 3]
		Chrompyrazole	610	$0,43 \cdot 10^{-5}$	0,1–1,0	[5, 8]
		Rhodamine 6G	610	$1,34 \cdot 10^{-5}$	0,025 – 0,4	[6, 11, 10]

Fig. 2. Scanned test scale for visual test determination of GeO_4^{2-} in the form of IA 12-MGK with astrafoxin on filter paper.

Experiment techniques

Preparation of β - $\text{GeMo}_{12}\text{O}_{40}^{4-}$ IA with astrafoxin: the necessary volumes of $1 \cdot 10^{-6}$ M Ge (IV) solution were added to 25 ml flasks to obtain concentrations of $0,04 \cdot 10^{-6} - 2 \cdot 10^{-6}$ mol/L, 0 each, 6 ml of $1 \cdot 10^{-2}$ mol/L Na_2MoO_4 solution, 0.5 mol/L H_2SO_4 solution to create the required pH (1.5-2.0). The reaction is fast. Then, 2 ml of a 0.6 M solution of tartrate acid were added, after which the molybdo germanic acid solution was re-acidified, 1.5 ml of 5 M H_2SO_4 . Then, in small portions, with constant stirring, 1 ml of 10^{-4} mol/L AF was added, and distilled water was brought to the mark.

Obtaining a test scale for the visual test determination of GeO_4^{2-} dynamic sorption was used. The resulting IA solution was passed through filter paper. Accelerated the passage of the solution using a vacuum pump. The resulting sample was removed from the column, dried in air, and then the resulting scale was scanned (Fig. 2).

In the absence of equipment for measuring diffuse reflection, colorimetric analysis is a simple and

affordable method that is not inferior in efficiency. Measurement of staining intensity of IA sorbates on paper.

The method of carrying out colorimetric measurements: the scale prepared for the above-mentioned method is scanned against a white background in the color image mode (separation ability 600×600 dpi or more) The brightness / contrast ratio is set to 30/0. Using the Paint graphical editor, cut out 170×170 or smaller pixels from the scanned image. For each pixel in the image, R, G, B – color coordinates [2] are calculated and averaged over the entire data array.

Results and discussion

We studied the optimal conditions for the formation of a colored ionic associate (IA) of a 12-molybdo germanium complex (12-MGC) with polymethine dye cations astrafoxin (AF) in a solution and its sorption on cellulose paper. The formation of the ionic associate AF-MGK was carried out in two stages.

At the first stage, a yellow oxidized molybdo germanium complex was obtained by

acidification of a mixture of solutions that contain GeO_3^{2-} and MoO_4^{2-} .

The second acidification was carried out to prevent the formation of persistent IA Astraflorin with isopolymolybdate ions. The excess of molybdate ions was masked with hydroxy acids.

The reaction of the formation of IA MGK with astraflorin occurs instantly. The reaction is selective with a fairly high sensitivity. The selectivity of the formation reaction may be impaired by the formation of colored IAs with large anions, but their solubility is much greater than the solubility of IAs with heteropolyanions. Therefore, there is no interfering effect of such anions: HCO_3^- , SO_4^{2-} , NO_3^- . Table 2 shows data on the effect of a number of ions on the determination of germanate ions.

Table 2. The maximum excess of foreign ions that does not affect the determination of Ge (IV) in the form of $\text{GeMo}_{12}\text{O}_{40}^{4-}$ with AF. $C(\text{Ge})=4 \cdot 10^{-7}$ mol/L.

interfering ion	Na^+ , K^+ , Mg^{2+}	NO_3^- , Cl^- , AsO_4^{3-}	Ni^{2+} , Zn^{2+} , Cu^{2+}	Fe^{3+}	CO_3^{2-} , PO_4^{3-}	SiO_3^{2-}
molar ratio $C_{\text{Ge}} : C_X$	1:1000	1:500	1:400	1:100	1:50	1:5

The decrease in the interfering effect of silicates in the determination of germanate ions is explained by the fact that the reaction for the formation of MGC proceeds in a more acidic environment. In this pH range, molybdosilicate is not fully formed. In this case, the molybdosilicate complex (MSC) is formed very slowly for 15-20 minutes, and the molybdogermanate complex – quickly, 1-2 minutes.

We have for the first time shown the possibility of a highly sensitive visual test determination of Ge (IV) after selective concentration of IA 12-MGA with polymethine dye AF.

Calibration graphs were obtained for the colorimetric determination of Ge (IV) in the coordinates of the R and B functions (red and blue) – $\log C$ (Table 3) or $(255-G)^2 / 2G = f(C)$ and the possibility of correlation of this dependences with spectrophotometric in coordinates A – $(255-G)^2 / 2G$.

Table 3. Color coordinates R, G, B obtained after scanning stained samples of filter paper with sorbed IA $\text{GeMo}_{12}\text{O}_{40}^{4-}$ - AF

$C_{\text{Ge}} \cdot 10^{-6}$, mol/L	R Color	G Color	B Color	$\lg(C)$
blank test	243	242	241	0
0,04	230	196	186	-7,398
0,2	188	177	127	-6,699
0,4	154	169	99	-6,398
0,6	135	134	68	-6,222
0,8	127	87	39	-6,097
1	113	79	24	-6,00
2	92	44	12	-5,699

The dependence of the R, G, and B color coordinates on the concentration of IA is exponential (Fig. 3.a, Fig. 3.b). R and G color coordinates upon IA $\text{GeMo}_{12}\text{O}_{40}^{4-}$ - AF sorption change most naturally and

in a wider interval. Data were processed using the modified Kubelka-Munk equation (Fig. 4). The equation of the calibration graph in coordinates $(255-G)^2 / 2G = f(C)$, where G is the value of the color coordinate R, and C is the concentration of Ge (IV) in mol/L, is described by the expression $(-4,1 \pm 1,5) + (3,16 \pm 0,11) \cdot 108 \cdot C \text{ Ge (IV)}$, the correlation coefficient is 0.995. The detection limit calculated by the $3S_a / b$ formula is $4 \cdot 10^{-8}$ mol/L.

Fig. 3.a. Dependence of coordinates R - functions of Ge (IV) concentration after sorption $\text{GeMo}_{12}\text{O}_{40}^{4-}$ - AF

Fig. 3.b. Dependence of coordinates B - functions of Ge (IV) concentration after sorption IA $\text{GeMo}_{12}\text{O}_{40}^{4-}$ - AF.

Calibration graphs were obtained for the colorimetric determination of Ge (IV) in the coordinates of the R and B functions (red and blue) – $\log C$ (Table 3) or $(255-G)^2 / 2G = f(C)$ and the possibility of correlation of this dependences with spectrophotometric in coordinates A – $(255-G)^2 / 2G$.

The need to analyze many different objects for the content of germanium requires the development of simple sensitive methods for a preliminary assessment of their content for the correct further selection of quantitative methods.

The developed method for the determination of germanium in the form of AF-12-MGK IA was used and

tested in the analysis of coking coal and iron ore. For analysis, we took coal from the coke-chemical plant in Kryvyi Rih, and iron ore from the Krivorozhskoye deposit. In coke-chemical production, the bulk of germanium remains in coke and only a small amount goes into tar water and tar. Coking coal is one of the sources of germanium production. The correctness of the results was monitored by the standard method (Table 4) using phenylfluorone. Also, the method of verification of model solutions (Table 5).

Fig. 4. Calibration chart for colorimetric determination of Ge (IV) in the form of IA KF with 12-MGK. Dependence of the modified Kubelka-Munk function on the concentration of germanium (IV).

Table 4. The results of the determination of Ge (IV),
 $\alpha = 0.95, n = 6$

object of analysis	colorimetric determination of IA AF with 12-MGK, discovered Ge ($X_{cp} \pm \Delta$), % (S _r)	Standard determination procedure using phenylfluorone, discovered Ge ($X_{cp} \pm \Delta$), % (S _r)
coking coal	$(2 \pm 0,08) \cdot 10^{-6}$ (0,03)	$(1,67 \pm 0,06) \cdot 10^{-6}$ (0,04)
iron ore	$(1 \pm 0,08) \cdot 10^{-6}$ (0,04)	$(1,25 \pm 0,06) \cdot 10^{-6}$ (0,04)

Table 5. Results of visual-test determination of GeO_3^{2-} in model solutions by the introduced-found method
 $(P = 0,95, n = 6)$

sample	Introduced Ge ^{IV} , µg/l	discovered Ge ^{IV} , ($X_{cp} \pm \Delta$), µg/l			
		proposed method	S _r	Method with phenylfluorone	S _r
drinking water "Bon Boisson"	58,0	59,4 ± 2,5	0,03	58,5 ± 2,0	0,03
distilled water	14,5	14,7 ± 0,14	0,04	14,6 ± 0,14	0,03

Thus, the possibility of using colorimetry in the analysis is confirmed, but not as a substitute for spectrophotometry, but as an element of preanalysis. In

spectrophotometry, integrated spectral characteristics are measured, in colorimetry, the components of color, that is, the color is differentiated into components. These are the so-called primary color coordinates: red (R), blue (B) and green (G) [13].

Calculations of these coordinates, their relationship with the concentration of the colored substance can increase the sensitivity of the determination, recognize shades, find steps for varying the concentrations in the manufacture of visual test scales.

Colorimetry, as a method of objective color measurement with computer processing of data, is widely used in industry: printing, varnishing, textiles, food, pharmaceuticals, and also began to be used in analysis.

At the moment, colorimetry is distinguished as an independent physicochemical research method. Colorimetry can be a powerful tool in material science, visual express analysis. In the literature they give recommendations for constructing color scales. There is an opinion that the minimum step of the scale corresponds to the Golden Ratio (Fibonacci number), the use of which minimizes the error of analysis [14].

Compared to the standard spectrophotometric method using phenylfluorone, the test method using astrafloxin has several advantages:

- is the lower definition threshold
- speed of determination
- greater availability of materials and reagents
- ability to use for on-site analysis
- no need to use expensive equipment.

At the same time, the disadvantages of the test method are:

- less reliability
- the method is semi-quantitative.

Thus, the test method cannot claim to be used in precision research, but can be used for educational research and approximate content assessments of Germanium.

The use of test systems in onsite analysis as part of the training course is one of the elements of sustainable development in learning.

Students gain an understanding the ability to determine micro-quantities Germanium is an important aspect of the eco-chemical assessment of the environmental impact of industrial enterprises. of chemistry for sustainable development as a new approach to the planning and implementation of chemical reactions and chemical processes. He learns that at the planning stage of the experiment, an assessment is needed not only of the target chemical properties of the future product, but also an assessment of environmental risks.

Currently, this method of the semiquantitative determination of germanium is used in laboratory and chemical practice at the Kryvyi Rih State Pedagogical University. As part of the analysis in place. The experience of use showed the simplicity and accessibility of performing operations to prepare a test scale and subsequent colorimetric analysis.

During the chemical training students studied the water of various reservoirs (including man-made ones)

of the city of Kryvyi Rih and surrounding areas. The study was conducted on many parameters, including the definition of Germanium. Germanium is a potentially dangerous element for human health [15].

However, the results of research over the last 5 years show that the content of Germanium, even in man-made reservoirs, does not exceed 1 µg/l. This is due to the rather low mobility of inorganic compounds in Germanium. It also shows that there is no potential environmental threat from Germany in such an industrial region as the city of Kryvyi Rih.

The hypothesis about the influence of electrical phenomena on geological processes and global disasters

*Arkadiy Plugin, Andrii Plugin, Oleksii Pluhin, Dmytro Plugin, and Olga Borziak**

Ukrainian State University of Railway Transport, 7 Feuerbach Sq., Kharkiv, 61050, Ukraine

Abstract. Global Warming is officially recognized as one of the aspects to the Earth's climate change; and its major factor is a sharp anthropogenic increase in concentration of greenhouse gases, especially carbon dioxide (CO₂). However many scientists do not agree with this view and do not consider the anthropogenic factor as its basic reason, thus regarding measures for limiting greenhouse gas emissions as useless. The authors believe that a real reason is lack of unequivocal ideas in the framework of the Earth Science. The objective of the research presented in the article is to establish true reasons for global catastrophes, global warming, their rapid increase of recent decades, and their hazard level, as well as to reveal their nature and actual mechanisms. The authors critically analyzed and compared the existing data on global processes and catastrophes on Earth from ancient times to nowadays, revealed their actual mechanisms on the basis of Submicro- and Macrocolloid Chemistry and Physical-Chemical Mechanics of Earth, a new science on Earth set up by the authors. The authors demonstrated that the motive power of all global phenomena and processes on Earth is the electric force, conditioned by the surplus negative electric charge of Earth, and the reason of the approaching global catastrophe is an abnormal increase of the charge in recent decades. The article deals with critical analysis of experimental data on dynamics of global catastrophes, among them the change in Earth's temperature and level of ocean, a greater amount of carbon gas and atmosphere dust.

1 Introduction

Global Warming is officially recognized as one of the aspects to the Earth's climate change; and its major factor is a sharp anthropogenic increase in concentration of greenhouse gases, especially carbon dioxide (CO₂). Global warming mainly manifests itself as a rapid increase in Earth's temperature, a change in the warm Gulf Stream current, etc. of last decades. International treaties recognize that the key measure to prevent the warming is compulsory reduction of greenhouse gas emissions, which consumes huge funds and physical recourses. However, many scientists do not agree with this view and do not consider the anthropogenic factor as its basic reason, thus regarding measures for limiting greenhouse gas emissions as useless. Many people can realize the approaching catastrophe but they do not know how to resist and what they should do. According to some researchers the reason of global warming is lack of veritable knowledge about the world and man. We believe that a real reason is also lack of unequivocal ideas in the framework of the Earth Science.

Unlike the existing science and "alternative" sciences, the authors established an actual reason and revealed the mechanism of these global cataclysms and natural disasters, revealed mechanisms of the Earth development and imminent global catastrophes, and, furthermore, critically analyzed existing experimental data on the global catastrophes' dynamics.

In recent decades the number of natural disasters in the world has rapidly increased.

It is considered that the reason is in the Earth's global climate change, in particular, a higher temperature and the anthropogenic increase in the greenhouse gas concentration since 1960, especially CO₂ and methane (CH₄), (it is shown in Fig. 1 as the first maximum), a change in the warm Gulf Stream current, etc. As it was mentioned above, international treaties (the Kyoto Protocol of 1999, the Paris Agreement of 2015) consider a compulsive reduction of greenhouse gas emissions as the key measure to prevent these catastrophes; therefore, this requires great funds and physical recourses.

However, there are some other views on the problem. As many scientists think, particularly in [1-3], Earth's global warming has not been caused by the CO₂ emissions to the atmosphere, but, on the contrary, by a higher temperature of Earth; as there is no record about anthropogenic contribution into an average annual temperature rise on Earth, we can suppose that the international treaties are not practical and rather useless. We believe that the reason is lack of the genuine knowledge about the world and man, and, actually, the erroneous nature of the Earth Science.

2 Research methodology

The methodology of the research is based on Submicro-

* Corresponding author: borziak.olga@gmail.com

and Macrocolloid Chemistry and Physical-Chemical Mechanics of Earth, a new science established by the authors that was published in book “Submicro- and Macrocolloid Chemistry and Physical-Chemical Mechanics of the Earth” in 2016. The science is based on laws and regularities of Colloid Chemistry and Physical-Chemical Mechanics of Dispersed Systems and applied to subjects of inquiry of the submicro- and macrocosms. Their applicability is conditioned by the fact that Colloid Chemistry and Physical-Chemical Mechanics [4, 5] considers the surface phenomena, in particular, electrosurface characteristics of disperse systems. Earth is also considered a disperse system, with a scale of $<10 \text{ \AA}$ and $>>1 \text{ \mu m}$, going far beyond the colloid sizes ($10 \text{ \AA} \div 1 \text{ \mu m}$), where electrical surface phenomena, processes and regularities are also prevalent.

Fig. 1. Number of reported disaster events: drought, floods, extreme temperature, landslides, wildfires, volcanic eruptions, earthquakes and other. *Source:* EM-DAT (2019): OFDA/CRED International Disaster, Université catholique de Louvain- Brussels-Belgium.

The used methods are theoretical and analytical and based on generalization and critical analysis of existing literature data in the field of global phenomena and processes on Earth. Regularities that are used for analysis: Coulomb electrostatic forces, polarization, diffusion, osmosis, capillary rise, etc.

3 Analytical review

Previously, the authors on the basis of the provisions of colloid chemistry and physico-chemical mechanics have studied the electrical effects on building structures and materials. For example, the construction of electrified railways, which are operated under the conditions of electrical influences from sources of direct [6] and alternating current [7]. It was shown and experimentally proved in [6] that under the influence of a pulsating unidirectional electric potential and the corresponding current flowing during the passage of trains, concrete and masonry mortar also undergo electrocorrosion. Electrocorrosion consists in electromigration leaching of Ca(OH)_2 [6] and the formation of cracks [8-10], the intensity of which depends on the current strength [6]. It was shown in [6, 10, 11] that the electrical effects on concrete and structures made of it are not only electric

potentials and leakage currents, but also excess electric charges. Excessive charges are formed during the macro-polarization of objects, both artificial and natural, from the unevenness of the Earth's electric field on the ground, from the transfer of cations of soils, rocks and concrete by ground and underground waters, temporary and permanent streams. Based on electrical measurements, schemes have been developed for the flow of leakage currents from rails of an electrified direct current railway track through structures that are in good agreement with the nature of corrosion damage. The effect of excess electric charges on the decrease in tensile strength of concrete [10], the deterioration of the physical and mechanical properties of soils as a result of their liquefaction [11] was experimentally confirmed.

Based on the understanding of these phenomena and processes, means have been developed to protect structures from electrical influences in the form of anodic or cathodic electrochemical protection, electro-drainage [12], grounded electrically conductive screens [6] or screens made of electrically conductive compositions based on mineral binders [6, 13] with simple or diode grounding, which drains leakage currents and stray currents. To protect structures from such currents it was proposed in [14, 15], to use screens-coatings with a polymer-cement mortar with increased electrical resistance, which will impede the flow of currents through the structure or reduce their strength.

By analogy with the proven regularities of electrical effects on building materials and structures, as well as the soil of the foundations, a hypothesis is put forward on the effect of electrical phenomena on geological processes and global disasters.

4 Results of research

On the basis of Submicro- and Macrocolloid Chemistry and Physical-Chemical Mechanics of Earth the authors revealed mechanisms of global phenomena and processes on Earth, such as a rapid growth in the number of natural disasters and catastrophes of recent decades, a higher temperature and greenhouse gasses (global warming), change of the warm Gulf Stream current, etc. In order to reveal these phenomena and processes and estimate their hazardous degree for the present civilization, the authors generalized and critically analyzed the global cataclysms and processes of ancient times, namely, the change in global temperature, the Sun's activity, greenhouse gasses, atmosphere dust, ocean level, extinction (or rather, disappearance) of organisms and humans, formation of supercontinents and their disintegration into continents, etc.

The moving force of the mechanisms and other phenomena and processes on Earth and beyond is the electric force induced by the surplus negative electric charge of Earth, and the reason of the approaching global catastrophe is an abnormal rise of this charge in recent decades.

The basic source of the charge is the thermal diffusion of electrons from the molten Earth's core as a result of a very big difference of temperatures in Earth's core (about

6000 °C) and on Earth's surface (14°C on the average), Fig. 2.

Fig. 2. Diagram of the excess negative charge of the Earth due to thermal diffusion of electrons from its red-hot nucleus to the surface

Such a notion of the surplus negative charge of Earth correlates with a diagram of Earth's spherical capacitor reproducing the hypothesis on ionosphere put forward by Nikola Tesla. It creates in the upper layers of Earth and its atmosphere the electric field, with the experimentally found average potential $E = -130$ V/m (corresponds to the equilibrium surplus negative charge), and near Earth's surface it changes from -1000 to +200 V/m.

Very intensive sources of Earth's surplus negative charge are also the Secular Sun's Activity and the periodic 11-year Sun's activity, Fig. 3, a.

In recent decades the most intensive source of the surplus negative charge has become space launchings (since 1957), from Cape Canaveral Air Force Station, the John F. Kennedy Space Center and the Wallops Flight Facility, mass launches of the super heavy Space Shuttle systems, and also Chinese rockets (Fig. 3, b, c and d, respectively). During the launch of a rocket, especially a heavy one, and the combustion of rocket fuel, a significant separation of electric charges occurs between the earth and the upper atmosphere.

Fig. 3. Space rocket launches: a – the Secular Sun's Activity and cycles of the 11-year Sun's activity. Compiled by [1]; b – rocket launches of 1970-2017 by China; c – rocket launches the Space Shuttle systems in 1981-2012; d – rocket launches from Cape Canaveral Air Force Station, the John F. Kennedy Space Center and the Wallops Flight Facility.

5 Mechanisms of the earth development and increasing global catastrophes

Let us consider mechanisms of basic processes and phenomena of the Earth development and imminent global catastrophes. The Earth's evolution has been accompanied by catastrophic processes for all living beings.

The surplus negative charge as the motive force for absolutely all global processes became apparent from the formation of Earth at least 5.5 billion years ago. Earth was formed when part of the accumulated surplus charge of the Sun as a molten mass corresponding to Earth's mass emitted to the Earth's orbit; it was provoked by thermal diffusion of electrons of the Sun (in the core the temperature is about 10,000,000,000 °C and outside – 6,000 °C).

About 1.4 billion years later in the cosmic vacuum with a temperature of 2,725 K (about -270 °C) the Earth surface with the world ocean became cool to the normal temperature and the first supercontinent Vaalbare appeared, Table 1.

Then, due to the constantly running thermal diffusion of electrons, a huge surplus negative charge accumulated under Earth's crust, the crust of the supercontinent

softened and fractures developed in it. These fractures accumulated the surplus negative charge of a very high concentration thus separating formed parts of the supercontinents great distances apart. And the supercontinent split into continents. It took about 100 million years.

Table 1. Formation of Supercontinents of Earth.

No	Supercontinents and Continents, years (billion/million years ago)	Beginning of existence (disintegration duration)
0	Earth, 4-5	
1	Vaalbara, 3.1–2.8	1.4
2	Kenorland, 2.7–2.5 (disintegration)	0.4 (0.1)
3	Nuna (Columbia), 1.8–1.5	0.9 (0.7)
4	Rodinia, 1.1–750 (disintegration of the previous one)	0.7 (0.4)
5	Pannotia, 600–540 (disintegration)	0.5 (0.15)
6	Pangaea, 300–180	0.3 (0.24)
7	Present Earth, 65	0.235 (0.115)

All these transformations of supercontinents and continents went along with influences of gigantic forces and cataclysms, when life could not exist yet. For the first time, as known, about 525 million years ago living beings appeared, and animals, such as amphibian and reptiles, about 300 million years ago, Fig. 4.

Fig. 4. The great extinctions of organisms on Earth during the period from 542 million years BC to present [16].

During their life the organisms regularly died out and disappeared, it might happen even on a massive scale:

1. The Ordovician–Silurian extinction events, 440 billion years ago (got extinct more than 60% of sea invertebrates).
2. The Late Devonian extinction, 380 million years ago (the number of marine communities reduced by 50%).
3. The Great Permian Extinction, 265 million years ago (got extinct more than 95% of all living organisms).
4. The Triassic-Jurassic extinction event, 210 million years ago (died out more than 50% of all types of living organisms known at present).
5. The Cretaceous-Paleogene, 65 million years ago (died out dinosaurs and 70% of all types of living organisms).

Life on land and relatively big animals appeared in the Carboniferous period. It is believed that the man appeared

2 million years ago.

Virtually all ancient developed civilizations, and there were several of them, disappeared. Nevertheless, they left for us megalithic structures build in recent ten-twenty millenniums, whose construction technologies cannot be applied at present.

One of the reasons why animals and people died out is also considered the constantly recurring Ice Ages or Glacial Periods (millions of years in duration).

Thus, the analytical research, presented in this section, confirmed that Earth's global processes (extinction of living organisms and people, and, consequently, vegetation, formation of continents and glaciers, orogenic processes, etc.) were chiefly caused and regulated by the periodically accumulated and dropped a huge surplus negative charge in the Earth's surface layers.

The fact, that most types of people ever lived on Earth became extinct, affords ground for a number of researchers to assume that all types of life have a limited period, and human extinction is inevitable (i.e. mankind always runs risk to die out) [17].

The significant factors of the global climate change on Earth are considered a rapid increase in temperature and greenhouse gasses, first of all, CO₂, and a change in the Sun's activity, Fig. 5.

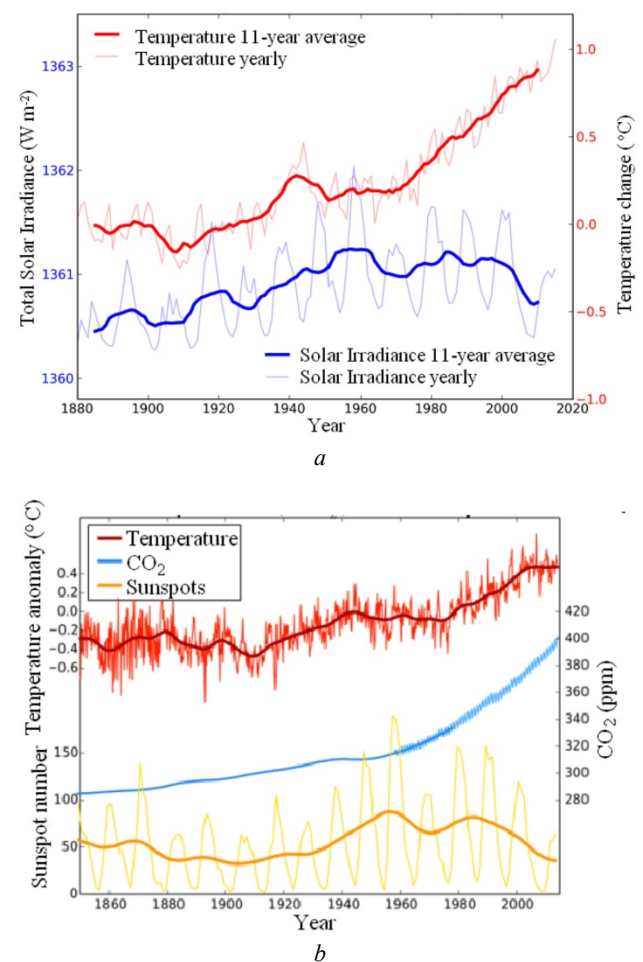

Fig. 5. Annual global temperature, Solar Irradiance and CO₂ change: a – compiled by Solar vs TemperatureSkeptical Science; b – schedule from Global Warming - Research IssuesStanford Solar Center.

Furthermore, "... last several hundred years the number of sunspots has constantly grown, and Earth has become warmer...", however since 1980 such a pattern has broken. Consequently, the Sun cannot be the main temperature regulator.

The relation between the Earth temperature, CO₂

concentration, and the number of sunspots testifies to their increase in concord and in cycles (Fig. 5). And diagrams in Fig. 6 presenting the last 400 and 800 thousands of years, based on diagrams from ice cores from Antarctica confirm it.

Fig. 6. Vostok ice core records for carbon dioxide concentration and temperature change (CO₂ lags temperature – what does it mean? Skeptical Science).

However, the concentrations have never reached such high values as we can witness today; this fact gives rise to serious concern of many researchers, Fig. 7.

Fig. 7. The change in the content of carbon dioxide (CO₂) during the last 400 thousand years and to present.

According to [18] "... the shape of a temperature curve advances the curve presenting the CO₂ changes by approximately 5-8 thousand years at the time when waters of the world ocean, the main reservoir of free CO₂ on Earth, completely got mixed (now the world ocean has approximately 60 times more of CO₂ dissolved than that in the atmosphere)".

According to diagrams presented, the concentrations of carbon dioxide (as methane) fluctuated in right cycles with a period of about 100,000 years. However, a more attentive study reveals that the CO₂ change actually follows the temperature change, with a delay close to one indicated.

The global temperature growth was also followed by an ocean level fall to approximately 100 m, Fig. 8.

The indicated periodic change in carbon dioxide (CO₂) due to its greater content in the ocean is conditioned by an increase in the surplus negative charge in the surface layer of the ocean water. It results in better solubility and increased concentration of CO₂ (mostly hydro carbonates and bicarbonates) in the ocean waters when CO₂ transfers to the atmosphere). A decrease in the surplus negative charge leads to crystallization of solution products. Accordingly, an increase or a decrease in the surplus negative charge during a long period (100 thousand years in average) leads to a cyclic long-term change in the temperature.

Accumulation of the surplus negative charge in Earth in recent decades, and thus, Earth's warming is the result of excessive rocket launches; and this leads to another Global catastrophe on Earth. Here, we can conclude that the CO₂ input into the atmosphere is not anthropogenic by nature, but the cause of Earth's warming is a huge increase in the surplus negative charge.

By the way, with an increase in the surplus negative charge in the ocean waters, not only CO₂ transfers to the atmosphere, but also the water itself; it happens due to its much more intensive evaporation, therefore water vapor is the most powerful greenhouse gas.

The data on long cyclic changes in both the amount of dust in the atmosphere and temperature cycles in ancient times and now obtained from ice cores of Antarctica are of considerable importance for studying Earth's global cataclysms, Fig. 8, Fig 9.

Such a substantial fall of the ocean level was conditioned by the previous rapid increase in the surplus

negative charge of Earth, which raised the ocean and sea waters along the soil capillaries by the macro

electroosmosis mechanism, thus lowering the ocean water level.

Fig. 8. The long cyclic changes in temperature and amount of dust in ice cores (atmosphere) during 800 million years (based on diagrams of [19] and [20]).

Fig. 9. The change in Earth's temperature from 100 million years ago to 0.5-3.5 billion years ago (the diagram is corrected by the period of dinosaur extinction – 65 million years ago) [16].

The surplus negative charge accumulated on soil and soil particles repulsed, the soil became loosened and atomized, and lost its cohesion. Their large surplus negative charge led also to emergence of repulsive forces

to the large negative charge in the Earth's surface layer. This force exceeded the gravitational force, and then the soil particles and the surface layer tore off and carried along virtually everything off the surface.

At earlier stages of its existence (0.5-2.25 billion years ago) the Earth temperature was about 25-47 °C with the maximum 1.75 billion years ago [21], which was quite acceptable for the beginning of life, especially in ocean. And in the earliest years of its existence, 2.25-3.5 billion years, the temperature was considerably higher, up to 70 °C, which was incompatible with life of most living organisms. The minimal temperature of 5 °C (about 65 million years ago) in the diagram (Fig. 9) when dinosaurs disappeared, coincides with the minimal ocean level (Fig. 8). Apparently, the second maximum ocean level (450 million years ago), Fig. 10, also coincided with the maximum temperature, this tendency manifested itself as the beginning of a temperature rise 500 million years ago.

Fig. 10. The change in the ocean level during the period from 540 million years ago (based on the diagram of [20]).

Such a change pattern in Earth's temperature and ocean level confirms that originally the surface temperature was very high, i.e. incompatible with any life on Earth. Approximately by a period of 1.5 billion years ago, the surplus charge of Earth reduced and reached the equilibrium state. Then it began to change in cycles relative to this equilibrium. The maximum negative charge resulted in global catastrophes, and then the surplus negative charge fell and began to rise again due to thermal diffusion of electrons from the Earth's core.

As we can see, the greatest changes in the ocean level coincide with periods of existence of the supercontinents (here, Pannotia and Pangea, Table, the minimal level) and their disintegration (the maximum level). The mechanism of their disintegration and formation is based on this dependency.

The main role of the surplus negative charge in all the global catastrophes is also confirmed by formation and disintegration of the supercontinents. During all its life the supercontinent accumulated a huge surplus negative charge underneath, and gigantic stretching forces grew in it. Moreover, the soil of the continent became softer, and the surface layers became loosened, crumbled up and dusted. When the stretching forces reached the limiting values, thus exceeding the supercontinent strength, cracks and splits developed inside, they accumulated a huge surplus negative charge from Earth's core; then the split parts went apart and formed continents.

Enormous amount of dust elevated off the Earth surface that was incomparable with the dust from eruption of the greatest volcanoes, the sunlight could not reach Earth for many million years, and the Earth temperature gradually fell. The cyclic changes in temperature and dust in ice cores of Antarctica convincingly demonstrate it (Fig. 8).

With the lapse of time the enormous surplus negative charge began to accumulate under and inside the formed continents owing to thermal diffusion of electrons from Earth's core. The charges and continents were polarizing acquiring the sequential unidirectional gigantic macro dipole moments towards the equator (due to a lag between the space vacuum and ocean water, and the Earth rotation (and the land on)), as well as in Earth's electric field between the poles. The attraction forces between these dipole moments redistributed the continents; the supercontinents joined and formed the supercontinent Pangea (Fig. 11).

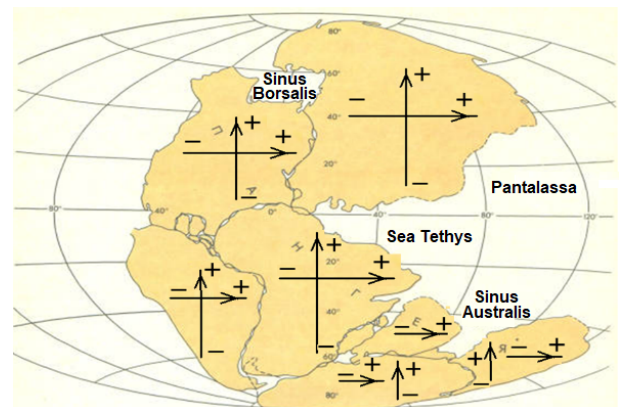

Fig. 11. The continent polarization and huge dipole moments of the continents the attractive forces between which resulted in the formation of the supercontinent Pangea.

A huge growth in the number of global catastrophes in recent decades, as it was mentioned above, has been conditioned by space rockets launches. The enormous number of these launches and launches of super heavy rockets to the Moon and Mars planned threaten to ruin the civilization in the short run.

6 Conclusions

1. Based on the provisions of colloid chemistry and physico-chemical mechanics of disperse systems and materials, a hypothesis has been put forward about the influence of electrical phenomena on geological processes and global catastrophes.
2. It is assumed that one of the moving forces of geological processes and global catastrophes is the excess negative electric charge of the Earth cyclically accumulated as a result of macropolarization phenomena.
3. The increase in the number of global disasters in recent decades has been influenced by space rocket launches. This effect is due to the fact that as a result of the combustion of rocket fuel, rocket take-off, a significant amount of electric charge is transferred, and it is divided between the earth and the upper atmosphere. A further

increase in the number of launches and mass of rockets may lead to an increase in the number of catastrophic events.

4. The prevention of catastrophic events is possible based on an analysis of the causes of the accumulation of excess charges, the development and implementation of ways to prevent such accumulation.

This research did not receive any specific grant from funding agencies in public, commercial, or not-for-profit sectors.

Abstract. Infrared spectroscopy (IR) is a highly effective method for the analysis of minerals, rocks and ores, capable of solving a whole range of problems when choosing innovative solutions for the technological processing of various types of mineral raw materials. The article considers the main directions of using the infrared spectroscopy method in assessing the technological properties of minerals and their behavior in technological processes: evaluation of the grade (quality) of mineral raw materials; analysis of the behavior of minerals in the technological process with prediction of their technological properties; analysis of changes in the structure and properties of minerals in technological processes; operational analysis of mineral substances at various stages of technological processing. The article illustrates all aspects of the use of infrared spectroscopy at various stages of studying the material composition of mineral raw materials in its enrichment assessment by specific examples of solving problems arising from the technological redistribution of various types of ore and non-metallic minerals.

1 Introduction

The modern stage of mineral processing is characterized by the involvement of increasingly poorer and more difficult-to-concentrate ores in the technological process. In this regard, there is a need for deeper study of their material composition at the level of recent advances in the field of crystal chemistry and crystal physics of minerals with the involvement of a wide range of the latest physical and chemical methods of analysis.

Infrared spectroscopy (IR spectroscopy) has been widely used in recent years in the practice of geological exploration. First of all, this is due to the high resolution of the method, its quickness, versatility and economy. The advantages of IR spectroscopy are most fully shown when studying the crystal chemical features of minerals such as polymorphism, isomorphism, coordination, and the degree of deformation of structural polyhedra. Considering the fact that these attributes are most widely demonstrated in the technological properties of minerals [1], it can be assumed that this method must take its rightful place in a wide arsenal of physical and chemical methods of analysis used for assessing the behavior of minerals at different stages of technological processing of ores of various types of minerals.

2 Publication overview

Nowadays the literature contains quite a few examples of the use of infrared spectroscopy in studies of various types of mineral raw materials in order to increase the efficiency of their technological processing. This research currently develops in two directions: geological-mineralogical and technological. Representatives of the former direction (V. Farmer [2], T. Shishelova [4], B. Pirogov [1, 6, 7, 9], A. Ivanov, J. Klopogge, D. Kamalova [18], E. C. Hecker, A. Remizov [14], R. Skochilov [18], I. Suvorova, N. Batyrshin, V. Stolpovskaya [18], A. Fishman [18], A. Smith [20], R. Frost [26-28], E. Malinowski [30], and the others) reveal signs that determine technological properties of rocks and ores when using infrared spectroscopy to diagnose qualitative and quantitative phase analysis of them, and establishing the crystal-chemical features of minerals. The technology research (Yu. Batura [10], B. Rivard, A. Jones, J. Miller [11], R. Clark [19], A. Guatame-Garcia [24], M. Buxton, R. Bedell [24], J. Kellar, R. Lima, P. Brandao, E. Giesekke, I. V. Solnyshkin, V. Chanturia [16, 22], I. Plaksin [25], etc.) are mainly based on the study of surface phenomena using infrared spectroscopy when fixing flotation reagents to minerals, as well as changing their properties under various external influences (thermal, radiation, ultrasound, etc.).

* Corresponding author: panteleva4y@gmail.com

The aim of the article is to analyze and generalize the available published data of the IR spectroscopy method in assessing the technological properties of minerals and their behavior in technological processes of ore processing.

3 Methods

The results of the author researches served as the real material of the article, the analysis of a number of the analogous works of the other authors was also presented. The IR-spectra study of minerals, rocks and the enrichment's products was made on the two-rays spectrophotometer Specord of "Carl Zeiss, Jena" firm (Germany) by the method of paste in the refined petrolatum oil. The intensity of the absorption's stripes was measured, according to the method of the basic line. The hardness of minerals was defined by the method of pressing on the PMT-3M hardness micrometer, but the dielectric penetration – by the sensor of Petrzhik. The content of the elements in minerals and products of the enrichment was determined by the method of the chemical analysis.

4 Results

Analyzing the information available today, we can say that infrared spectroscopy can be widely used at various stages of studying the material composition of mineral raw materials while assessing its enrichment; and it can solve various tasks of technological ore processing. Let us consider in detail the main ones.

4.1 Assessment of grade (quality) of mineral raw materials

One of the main characteristics of mineral raw materials is a combination of properties that determine compliance with its purpose. The separation of minerals into varieties plays a leading role in assessing the level of its quality.

IR spectroscopy is one of the most effective physical methods for assessing the grade of mined non-metallic mineral raw materials. Thus, studies of phlogopites ($\text{KMg}_3[\text{AlSi}_3\text{O}_{10}](\text{F}, \text{OH})_2$) from the Kovdor phlogopite-vermiculite deposit (Russia) showed that the infrared spectra of phlogopites enable to estimate their properties, including those that determine their quality or technological grade.

It was established [2] that phlogopites of various genetic types contain absorption bands with a maximum of 3700, 3660, 3620, 3550, and 3400 cm^{-1} in the region of stretching vibrations of OH groups. Typomorphic are mainly bands of 3550 and 3400 cm^{-1} . Absorption in the region of 3550 cm^{-1} is characteristic of multimolecular layers. They are quasi-solid structured entities. The band in the region of 3400 cm^{-1} corresponds to stretching vibrations of water in the bulk phase, the so-called film water [3].

Consequently, we have revealed the relationship between the intensity of these absorption bands and the

physical properties of the phlogopite of the Kovdor phlogopite-vermiculite deposit. So, Fig. 1 clearly demonstrates that the increase in the absorption coefficient at the maximum of the bands of 3550 and 3400 cm^{-1} leads to the decrease in the hardness of phlogopite, as well as the decrease in the dielectric constant of the mineral. T. Shishelova and co-authors [4] obtained similar data for phlogopites from deposits in Siberia (Russia).

Fig. 1. The relationship between the intensity of the bands of 3550 cm^{-1} and 3400 cm^{-1} of the IR spectrum of the phlogopite of the Kovdor deposit and its physical properties.

ICS method acquires the particular importance in assessing the grade of gemstone raw materials. The quality of a gemstone depends on many parameters, among which the most essential is the chemical composition and impurities.

Figure 2 shows the infrared spectra of aquamarines ($\text{Be}_3\text{Al}_2\text{Si}_6\text{O}_{18}$) of various grades. As can be seen from the above IR spectra, the region of stretching vibrations of OH groups of aquamarine depends on the grade of the raw material. Class 1 aquamarine has almost no absorption bands in the region of stretching vibrations of OH groups. As for class 2 aquamarines, we observe absorption in the region of $\sim 3640, 3580 \text{ cm}^{-1}$. Class 3 aquamarines have a wide absorption band with a maximum frequency of 3400 cm^{-1} , which is characteristic of free water. This is clearly expressed in the spectra of low grade aquamarine and is associated with the presence of defective sites where free and surface water is adsorbed. The presence of defective places affects the quality of the mineral. The same regularity is also characteristic of the region of deformation vibrations OH ($\nu = 1620 \text{ cm}^{-1}$) [5].

Fig. 2. The infrared spectra of aquamarines ($\text{Be}_3\text{Al}_2\text{Si}_6\text{O}_{18}$) of various grades [4]).

The revealed relationships allow us to provide an operational analysis of the grade of phlogopite raw materials. The operational analysis can be performed both on the basis of geological and technological testing and mapping of deposits, and as a result of selective express analysis in the process stream.

The selection of grades of mineral raw materials is often determined by its phase composition. For example, the possibility of using baddeleyite (ZrO_2) for the production of glazes is determined, first of all, by the concentration of phosphorus impurities. With its increased content, the glaze becomes dull, which reduces the quality of colored ceramic tiles. The presence of phosphorus in the baddeleyite concentrate of the Kovdor baddeleyite-apatite-magnetite deposit is determined by the presence of micro impurities of apatite ($\text{Ca}_5 [\text{PO}_4]_3 (\text{F}, \text{Cl}, \text{OH})$) in it. The content of P_2O_5 in the concentrate ranges from 0.05 to 0.93 %.

Apatite in baddeleyite concentrate is traced by the presence of information absorption bands in the regions of 640 and 670 cm^{-1} in the infrared spectrum of baddeleyite. They are responsible for the librational vibrations of the hydroxyl group of apatite. Figure 3 shows a histogram of the distribution of the intensities of the 670 cm^{-1} band in the spectra of 56 samples of baddeleyite monofractions. The whole sample is clearly divided into two groups. The right maximum corresponds to samples with a high content of apatite micro impurities (P_2O_5 content exceeds 0.54 %) which belong to the grade of substandard baddeleyite confined mainly to the zones of superimposed apatitization of ores of apatite-forsterite-magnetite composition. The left one corresponds to the samples with minimum apatite content suitable as a raw material for the production of glazes.

Fig. 3. Histogram of the distribution of quantities band intensities of 670 cm^{-1} in the spectra of mono-baddeleyite fractions of the Kovdor field.

4.2 Analysis of the mineral behavior in the process with prediction of their technological properties

For the efficient processing of mineral raw materials, it is extremely important to study the behavior of the entire complex of minerals (composing ores) at the technological stages of processing, such as crushing, grinding, separation, etc. Real minerals behave differently in technological redistribution because of defective structures, the presence of numerous impurities and inclusions. The task of researchers to control all these aspects, making recommendations for improving the processes of enrichment using a wide range of physical and chemical methods for the analysis of minerals and ores. So, it becomes possible to solve the problem of leading forecasting of technological indicators of ore processing.

For example, the crystal-chemical features of magnetite data obtained through IR spectroscopy are of fundamental importance for solving various problems of the magnetite ores enrichment. First of all, it makes possible to obtain data on assessing the balance of redistribution of useful and harmful elements-impurities in magnetite (FeFe_2O_4) upon receipt of iron ore concentrate [6], revealing the form of their occurrence.

For example, the infrared spectra of magnetites of the Gusevogorsky deposit are characterized by a similar texture type of mineralization (medium disseminated ores), but significantly different technological enrichment indicators. A shift of the ν_3 band to the low-frequency region 564 \rightarrow 545 cm^{-1} is noted (Fig. 4). The position of this band depends on the composition of the mineral and varies over a wide range from 526 cm^{-1} for hematite, which can be fixed as a product of magnetite oxidation, up to 575 cm^{-1} for stoichiometric magnetite [7]. IR spectroscopy unambiguously indicates an increase in the internal heterogeneity of Gusevogorsk magnetites. Particularly, the manifestation of isomorphic substitutions of Fe^{+3} for Ti^{+4} and the decomposition structures of magnetite-spinel, magnetite-ulvospinel solid solutions reduce the iron content in magnetite concentrate by more than 2 %.

Fig. 4. The change in the position of the ν_3 band in the IR spectra of magnetite of the Kachkanarsky deposit with increasing internal heterogeneity of the mineral (1 \rightarrow 2).

The infrared spectra of magnetite also make it possible to determine the contrast of the properties of magnetic separation of a mineral, taking into account the peculiarities of its crystal chemistry. Figure 5 shows the relationship between the position of the ν_3 band and the value of the coercive force (H_c) of specially selected magnetite samples from low-iron ores of the Kovdor deposit. The coercive force is one of the most important magnetic characteristics of the mineral which reflects the rigidity of the ferrimagnetic material, and its anisotropy and defective structure as a result. The value of the coercive force increases sharply with the violation of the uniformity of magnetite [6]. The presence of a clear inverse relationship between ν_3 and H_c of magnetite samples corresponds with these data. We note that the value of the coercive force of the mineral significantly affects the course of magnetic separation. With its increase, flocculation of crushed particles increases with the involvement of non-metallic minerals in the magnetic concentrate [7].

Fig. 5. Dependence of the position of the ν_3 band in the IR spectra on the value of the coercive force H_c of Kovdor magnetite samples.

The most high-temperature iron ore deposits are characterized by heterogeneity of the structure and heterogeneous composition of magnetite. The crystal-chemical features of the mineral are the main geological and mineralogical factor determining the ore dressability. Respectively, it is reasonable to select technological varieties of ores by using the crystal-chemical features of magnetite. The use of IR spectroscopy here is very effective. It becomes possible to construct geological and technological maps of deposits when mapping the typomorphic features of the infrared absorption spectra of magnetite.

In the infrared spectra of the apatite of the Kovdor deposit, there are two absorption bands that most informatively characterize and objectively fix the crystal chemical heterogeneity of the mineral. They are: a single absorption band in the region of 870–886 cm^{-1} , corresponding to the non-degenerate vibration ν_2 of the anion $(\text{CO}_3)^{2-}$, and also part of the asymmetric deformation ν_4 vibrations of the $(\text{PO}_4)^{3-}$ ion. There is a clear inverse relationship between the intensity of these bands, which obviously indicates an isomorphic mechanism for the entry of the CO_3 group into the position of the phosphate tetrahedron [7].

The result of this is the established inverse relationship between the intensity of the absorption

band of the $(\text{CO}_3)^{2-}$ group on the IR spectra of apatite in the region of 870 cm^{-1} and the P_2O_5 content in apatite concentrate (Fig. 6). This is caused by an increase in the structure of the mineral deficit of active Ca_2 ions, which directly interact with the flotation reagent, when phosphorus is replaced by carbon. As a result, the flotation activity of apatite decreases sharply and carbonate material is involved in the concentrate. There is also a decrease in the weight fraction of P_2O_5 in the composition of the mineral.

Fig. 6. The relationship between the intensity of the absorption band of the group $(\text{CO}_3)^{2-}$ in the IR spectra of apatite of the Kovdor deposit in the region of 870 cm^{-1} and the content of P_2O_5 in the apatite concentrate.

Thus, the IR spectra of the apatite of the Kovdor deposit make it possible to evaluate the contrast of the flotation properties of the mineral in ores of carbonatite complexes, and as a result, to predict the technological properties of ores. The described method for predicting the technological properties of apatite ores of carbonatite complexes is protected by copyright [9].

IR spectroscopy is widely used to study surface phenomena when fixing flotation reagents to minerals [10, 11, 19]. A study of the chemistry of reactions during the adsorption of anionic and cationic collectors makes it possible to conclude the place and nature of the fixation of the reagents, as well as to trace the change in surface properties when exposed to regulators.

4.3 Analysis of changes in the structure and properties of minerals in technological processes

The technological properties acquired by minerals under various influences should be considered as a dynamic process of superposition of constitutional (standard) and secondary (induced) properties [13]. The significant changes in various natural mineral properties (morphology, granulometry, constitution (crystal chemistry), etc.) begin as soon as it undergoes explosion (during mining), crushing, grinding (during processing) and any types of separation. B. I. Pirogov [6] states it is here that the influence of technogenesis due to external energy effects (mechanical, temperature, chemical, etc.) affects the change in the constitution of the mineral. Infrared spectroscopy allows to analyze effectively the dynamics of these changes.

Thus, for example, significant changes are observed in the IR spectra of the initial and ground Pechenga diopside ($\text{CaMg}(\text{Si}_2\text{O}_6)$). They are related to the appearance of new bands in the samples of the crushed mineral in the region of 3400 and 1640 cm^{-1} , which correspond to vibrations of the OH group. This indicates that during grinding there is a noticeable hydration of the surface of the mineral grains due to the presence of atmospheric one. In addition, the appearance of a double peak in the region of 1500 cm^{-1} is observed. The position of this peak corresponds to the absorption band of the carbonate group and is due to the absorption of carbon dioxide by mechanically chemically activated diopside [13].

The technological cycle of the “life” of the mineral continues after the processing of mineral raw materials. Thus, studies by M. S. Khokhuli with co-authors [13] find that in the IR spectra of the phlogopite of the Kovdor phlogopite-vermiculite deposit, the intensity of bands caused by vibrations of free water molecules and hydroxyl groups ($3700 - 1600\text{ cm}^{-1}$) increases in samples subjected to long-term storage in the underground conditions of the mine (more than 20 years). Consequently, it is proved that the structure of phlogopite changes with the formation of up to 5% vermiculite layers in it during the storage of phlogopite crystals. The changes caused by phlogopites hydration and partial decationation of sections of its crystals ultimately affect the significant deterioration of their technical properties.

The deformations of the minerals structure that occur under the influence of physical influences (temperature, radiation, ultrasound, electro-kinetic, etc.) are the most significant and interesting for technological purposes. Such deformations allow the directional transformation of their technological properties. Infrared spectroscopy provides the choice of the optimal modification method with a targeted change in the contrast of the separated minerals. This allows ultimately optimizing the technological scheme of processing of raw materials.

Figure 7 shows the results of an experiment we conducted when studying the temperature transformations of goethite of the Skelevat iron ore deposit (Kryvyi Rih). We recorded a series of intense absorption bands characterized by the stretching and deformation vibrations of OH groups in the infrared spectrum of goethite in the region of $3600-3200\text{ cm}^{-1}$ at room temperature [14]. It is observed a change in the spectral pattern in this region with a gradual heating of the mineral. To a temperature of 180°C is a gradual decrease in the intensity of the absorption bands of hydroxyl groups. A sharp decrease in the intensity of this band is observed at 190°C in the spectrum of the mineral, which again changes into its monotonic decrease at 200°C up to 600°C .

Such a change in the spectrum is associated with a gradual disruption of the $\text{FeO} - \text{O}$ bond with an increase in temperature to 190°C and a redistribution of the energies of all the bonds of the system. In the range of $190 - 200^\circ\text{C}$, a hematite structure begins to form along with goethite. A further increase in temperature (up to

600°C) leads to the gradual removal of hydroxyl groups and the formation of a stable hematite structure.

Fig. 7. Changes in the intensity of absorption bands in the region of $3600-3200\text{ cm}^{-1}$ in the IR spectra of goethite of the Skelevat iron ore deposit under temperature exposure.

A group of researchers led by V. Chanturia [16] studied the change in the composition of surface layers and the chemical state of atoms on the surface of galena (PbS) as a result of exposure to high-voltage nanosecond electromagnetic pulses. It was established that after an energetic effect on the mineral, an integrated change in the band area is observed in the range of $1000 - 1400\text{ cm}^{-1}$ of the IR spectrum. This change corresponds to the absorption band of the deformation vibrations of the $\text{H} - \text{O} - \text{H}$ bond, which indicates a change in the hydration of the surface of galena particles. This creates favorable conditions for adsorption of the anion collector and contributes to an increase in the flotation activity of galena.

4.4 Operational analysis of minerals at various stages of technological processing

The effective management of modern mining and processing operations is largely determined by the efficiency and reliability of information on the composition and properties of processed products at various technological cycles. So, much attention is paid today to the development of operational control methods both at the stage of extraction and processing of ores. This is especially true considering the fact that at the end of the 20th century models of portable infrared spectrometers, simple and affordable, with low cost, were developed and are widely available. Consequently, today there are already examples of the effective industrial use of IR analyzers [17, 18].

The IR spectrum of any substance (the position of the absorption bands, their intensity, width and shape) is individual, and can be used to identify this substance. The infrared spectrum of the mineral mixture is the sum of the spectra of the components of the mixture, and the intensity of the absorption bands in the spectrum of each component is proportional to its content in the mixture [15].

Thus, the principle of additivity of IR spectra makes it possible to develop an inexpensive express analysis on the

basis of this method in the cycle of geological and technological control of mining and processing enterprises.

A number of examples of this application of infrared spectroscopy are given in the modern literature [26]. The main focus of these works is the development of methods for increasing the accuracy of analysis. So a group of researchers led by R. A. Skochilova proved that in this case the baseline method traditionally used for the quantitative analysis of minerals by their IR spectra is ineffective [19].

This is due to the fact that the spectra of matrices (batch, core and other products of various cycles of technological conversion) can vary within significant limits, and to a greater or lesser extent overlap the analytical bands of the analyzed mineral. The authors suggest using mathematical-statistical information processing and, in particular, the factor analysis method. This approach allows to find individual spectra and concentrations up to an arbitrary factor from a set of experimental spectra of a mixture with different contents of components. The advantage of this approach is that the IR spectra of several mixtures are analyzed simultaneously in a wide spectral range, and baseline measurements are not required to extract quantitative information.

5 Conclusion

Infrared spectroscopy is a highly effective method for the analysis of minerals, rocks and ores, capable of solving a whole range of problems when choosing innovative solutions for the technological processing of various types of mineral raw materials. The main areas of application of IR spectroscopy are: assessment of grade (quality) of mineral raw materials; analysis of the behavior of minerals in the technological process with prediction of their technological properties; analysis of changes in the structure and properties of minerals in technological processes; operational analysis of mineral substances at various stages of technological processing. The article provides numerous examples of this use of the IR spectroscopy method. The information capabilities of the infrared spectroscopy method are significantly expanded when it is used in combination with other physical and chemical methods of analysis: X-ray diffraction, thermal, electron paramagnetic resonance, scanning microscopy, etc.

The direction of further research is the application of the infrared spectroscopy method in the development of new technologies for the extraction of useful components based on nanotechnologies.

Abstract. During the design and operation practice, it is necessary to assess the possibility of deformation of structures located on foundations which are able to precipitate and subside. Only with reliable and accurate determination of the stress-strain state of structures of structures together with soil masses during modeling, it is possible to apply the finite element method in practice. The calculations using the PLAXIS and LIRA programs made it easier to analyze the stress-strain state of the soil mass and the stability of retaining walls: I option is corner retaining wall; II option is retaining wall with a structural surface. With the same soil base (layer geometry and physicommechanical properties), loads and boundary load conditions, it is obvious that for the II option the entire mass of soil is included in the work and the stresses are uniformly distributed over the front and foundation plates (over common stresses), uniform structural deformations are observed and soil base, which, in turn, ensures the stability of the retaining wall (according to the general picture of movements) The validity of the theoretical forecast of the behavior of engineering structures interacting with an unevenly deformed base cannot be obtained on the basis of the regulatory framework. This gap can be filled in when modeling the “base – engineering structure” system using modern calculation programs using the finite element method.

1 The problem and its relationship with scientific and practical tasks

Retaining walls are now widely used not only in civil and industrial construction, but also in urban planning for complex landscapes.

There are situations of construction of objects in cramped conditions, in adverse territories with active acting deformation influences, which makes the use of existing types of retaining wall structures more complicated. An important factor in solving the emerging problems is the high level of expertise on engineering and geological conditions in large industrial cities, especially in regional centers. Modern research is mainly focused on clarifying the geotechnical nature [1].

As earlier experience shows, the development of hazardous processes in urban areas continues. First of all, these are the processes of flooding in the territories, the development of landslide deformations, subsidence of the surface above mine workings, subsidence of loess soils, etc. These processes are associated with a decrease in serviceability or deformation and the destruction of buildings and structures.

According to expert estimates, 90% of the territory of Ukraine is characterized by complex engineering and

geological conditions, worsening due to the influence of natural and technogenic factors.

As for the Kryvyi Rih city, the technogenic load on the geological environment is several orders of magnitude higher than for other adjacent cities. It should be especially noted that iron ore has been mined for about 200 years, up to 47% of the built-up territory is located in the developed space. In modern practice, the construction of facilities in cramped conditions, in areas subject to adverse physical and geological processes, complicates the use of existing types of retaining wall structures. Extremely unfavorable combinations of underworking with subsidence of soils, with flooding, etc. are encountered, therefore, in order to protect the settlements, industrial facilities, utilities and transport communications with a certain level of safety, it is necessary to use engineering structures of a special type that would perceive the influence of variables of engineering -geological, natural and technogenic factors.

Building on a deformable foundation is very widespread. In recent years, as the territories that are most favourable for development have been exhausted, construction in territories with difficult conditions, which are characterized by significant uneven deformability of the base, has become increasingly widespread [2, 3].

Engineering methods of calculation, which are traditionally used in design, cannot answer all questions

* Corresponding author: radomirtimchenko@gmail.com

of operational practice. Widespread in many countries are programs based on the finite element method (FEM). These programs have a fairly wide scope and according to them it is possible to determine the stress-strain state, including structures, in the “base – engineering structure” system [4-7].

2 Analysis of research and publications

Complicated engineering and geological conditions - this is a geological environment that includes specific soils, hazardous natural or technogenic processes, geomorphological conditions, geological and hydrogeological factors of interaction with buildings and structures, belong to the II and III category of complexity of engineering and geological conditions [8, 9]. Many scientists have devoted their work to determining the lateral pressure of soil on retaining walls, taking into account their joint work with the soil mass.

So, V. Raiuk [10, 11] investigated the nature and magnitude of the lateral pressure on the vertical face of the retaining wall, taking into account its deformation and displacement, using the model of linearly deformable half-space, but he did not consider the joint work of the vertical wall and the foundation as a single system that interacts with soil. K. Chernyshova [12] investigated the effect of the flexibility of a vertical wall on the lateral pressure of the soil.

Y. Luchkovskiy [13], using the superposition method, provides a solution for determining the lateral pressure of soil on retaining walls from narrow loads and concentrated force. He draws attention to the attenuation with a deepening of lateral soil pressure from the load. However, these authors, when determining the lateral pressure, did not take into account the joint work of the vertical wall and the foundation as a single system that interacts with the base.

Y. Symvulydy [14] calculates a flexible retaining wall taking into account the interaction of all its elements with the base, but introduces a linearly deformable half-plane as a model of the natural base, which is not entirely correct. In addition, this method does not allow taking into account the influence of the loading on the stress-strain state of the system.

A significant amount of research has been devoted to the static calculation of retaining walls [15, 16]. The number of works on the dynamics of these structures, especially taking into account the elastic properties of their materials, is much smaller [17, 18]. Usually, dynamic calculations are performed if pulsed, vibrational or moving loads act on the structure [19].

3 Formulation of the problem

When constructing retaining walls in complex engineering and geological conditions, it is necessary to achieve:

- increasing the stability and strength of retaining walls;
- reducing the cost of used building materials;
- decreasing in the volume of earthwork; reduction of strain unevenness;

- reduction of construction time;
- improving the conditions of filling and compaction of the filling;
- increasing operational reliability, quality of work and increase the service life of retaining walls.

Thus, to assess the stress-strain state of retaining walls, it is necessary to take into account the joint work of the entire wall with soil and the use of more reasonable soil models in the region of its vertical and horizontal elements.

The aim of the research is to study the stress-strain state of the base and retaining wall with a structural surface (PSSP) taking into account their contact interaction to increase the stable operation of the “base – engineering structure” system.

4 Statement of material and results

The most common engineering structures in urban design today are retaining walls that are used for fencing:

- slopes of embankments and excavations within the area and access railways and roads in case of inability of carrying out slopes with the necessary inclination;
- pits during the construction process when it is impossible to perform slopes with the necessary inclination;
- special structures – ramps, bulk materials warehouses, bunker overpasses and ore yards of metallurgical plants;
- individual overpriced or underpriced sections of technology located within and outside buildings according to technology conditions.

Since ancient times, massive retaining walls of stone blocks and slabs have been used to support slopes, excavations, embankments and natural slopes. Technical progress and the laws of economic efficiency draw attention to the design features of the retaining wall and the characteristics of the interaction of the foundation with it. Important issues are optimizing the design of retaining walls, taking into account the following characteristics:

- the maximum inclusion in the work of soil filling;
- decreasing the values of the active soil pressure;
- increasing resistance of the displacement along the sole of the retaining wall;
- minimization of material consumption.

An important factor in solving the tasks is a high level of knowledge of engineering and geological conditions in large industrial cities and regional centers. Modern research is aimed at clarifying mainly geotechnical nature. The experience of recent years shows that the development of hazardous processes in urban areas continues. First of all, these are the processes of flooding of territories, the development of shear deformations, subsidence of the surface above mine workings, subsidence of loess soils, etc. These processes are associated with a decrease in serviceability or deformation, destruction of buildings and structures [2].

It is not always possible to use well-known technical solutions in the undermined territories and subsiding soils with complex deformations of the base, since they are not suitable for these working conditions. The existing structures of retaining walls are not designed for

additional efforts from horizontal displacement or vertical movement of the soil, which causes stress concentration in the lower part of the front plate and, of course, will lead to the destruction of the structure.

Therefore, there was a need for the use of new designs that would take into account these shortcomings and increase the reliability of operation of unsuitable territories.

A retaining wall is proposed, which can be used to stabilize unstable slopes and gradients, as well as in undermined areas with horizontal and vertical movement of soil (Fig. 1–4) [20].

Fig. 1. Structural retaining wall.

Fig. 2. Node A.

Fig. 3. Section A-A.

Fig. 4. Node B.

The new design of the retaining wall with a structural surface can be used to protect the territory from collapse. It represents an improvement of the monolithic retaining wall of the corner type by forming contact surfaces with cavities on the vertical and foundation elements from the ground, which allows to reduce the peaks of contact stresses on the surface of the vertical element of the retaining wall due to the uniform redistribution of pressure in the approaching soil, to increase the shear resistance along the sole retaining wall, in addition, in the case of additional uneven deformations of the base acting on the foundation the element, to improve its operation, which allows a retaining wall to perceive and evenly redistribute the efforts of complex loadings.

The monolithic retaining wall of the corner type includes vertical and foundation elements, and on the surface of the vertical and foundation elements, alternating support parts and cavities are placed on the contact side, while the cavities are made in the form of truncated pyramids of the same size and directed by a smaller base into the vertical element, while the volume cavities is determined by the formula:

$$V = \frac{2 \cdot \omega_{\phi} \cdot N \cdot H \cdot (K \cdot (\delta + h) - h)}{n \cdot R \cdot (H - \delta - h) \cdot [1 + (\cos \alpha + f \sin \alpha)]}, \quad (1)$$

where: V is the volume of cavities; N is the external normal load relative to the envelope surfaces of the supporting parts, which acts horizontally; R is the ultimate bearing capacity of the soil at which the static equilibrium of the retaining wall is established and maintained; H is total depth of the cavities; h – is the depth of penetration of the soil into the cavity; δ – is the absolute value of the forced displacement of the soil at the considered point; S – is the actual contact area of the supporting prismatic sections; K – is the safety factor for the contact area, which takes into account possible changes in the estimated power loads; f – is the coefficient of friction between the soil and the supporting prismatic sections; ω_{ϕ} – is the generalized coefficient for taking into account the shape of the volume of prismatic sections and their projection area along the envelope surfaces of the supporting parts; n – is the coefficient of conversion of contact pressures into their projection on the normal axis to the envelope surface of the supporting parts; α – is the angle formed by the envelope of the plane of the supporting parts and the tangent plane, which is drawn to the surface of the prismatic sections at a height h .

For a smooth perception of deforming actions from moving soil to a vertical element and deforming actions from vertical movement of soil to a foundation element, lateral faces of the planes are rounded. To reduce the effective friction forces on the vertical element, lateral faces of the planes are coated with an antifriction layer. To compact the backfill soil and to prevent the penetration of soil into the cavity, a sheet of resilient material is placed on the contour surfaces of the supporting parts.

The proposed retaining wall 1 consists of a vertical element, which has cavities 2 and supporting parts 3, in the direction of action of the shifting soil, and a foundation element, which has cavities 2 and supporting parts 3, in the direction of action of the vertically moving soil.

The backfill soil 4 and the base soil 5 are directed into cavities 2, which have the shape of truncated pyramids, with bases 6 and side faces 7. Side faces 7 and cavities 2 constitute the actual side surfaces of the support parts 3.

Facets 7 form ribs 8 in the plane of the bases 6, which make up the envelope surface of the supporting parts 3 (Fig. 5–8).

Fig. 5. Design schemes: a) I option; b) II option.

On the enveloped vertical surfaces of the supporting parts, between the soil and the cavities, depending on the type of soil conditions and the nature of the deformations, a sheet of resilient material 9 can be placed.

The soil directed into the cavity is in contact with the side surfaces of the supporting parts 3 by the supporting prismatic sections 10 of the side faces 7 of the cavities 2. An antifriction layer 11 can be made on the surface of the supporting parts, which is placed on the surface of the retaining wall.

With the development of the deforming load, that is, with vertical and horizontal movement of the soil relative to the retaining wall 1, after its installation, the soil penetrates into the cavity.

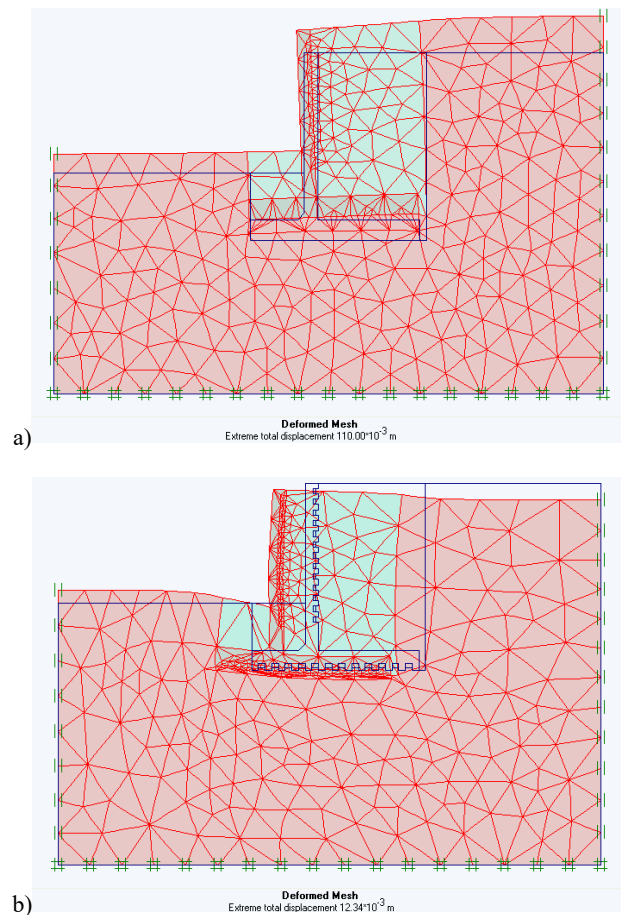

Fig. 6. Deformation of the mesh of finite elements: a) I option; b) II option.

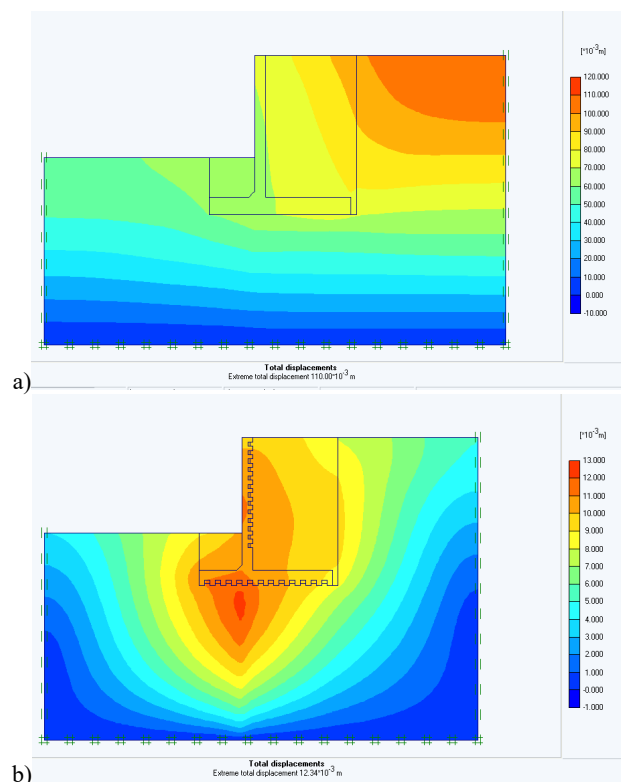

Fig. 7. Complete movements: a) I option; b) II option.

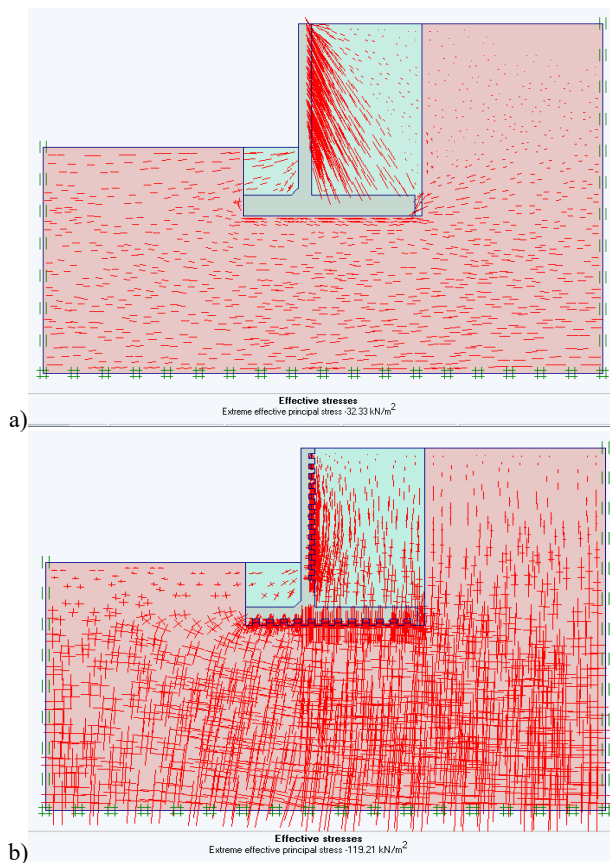

Fig. 8. Effective stress σ_{ef} : a) I option; b) II option.

Regarding the vertically built enveloping planes of the supporting parts 3, the vertical and foundation elements of the retaining wall 1, the acting loads in ordinary geotechnical conditions are the active lateral pressure of the soil 4 backfill and the pressure from the dead weight of the retaining wall 1.

The retaining wall is in stable equilibrium position, and the plane of the supporting prismatic sections 10 are proportional in depth to the ordinates of the lateral pressure and the weight of the retaining wall 1, with the such limiting soil resistance under which it is held in statically balanced position.

Under the conditions of detection the actions of forced horizontal and vertical displacements of the soil, normal loads along the front of movement of the soil are transformed into frontal passive pressure, and in the direction of movement they cause lateral friction, and in all cases they are applied to individual supporting parts 3 at an angle and much larger than the usual active soil pressure.

In this case, an increase in contact pressure at the prismatic support sections 10 above the limiting values in statics is impossible and also leads to the fact that the soils 4, 5 which are imposed on the contact are plastically destroyed and freely move in the cavity 2 until deformation effects are manifested.

The shape of the cavities 2 (truncated pyramid) is most efficient for soil compaction. Soil, falling into the cavity in the region of the lower base of the pyramid and passing the path to its upper base, spontaneously compact.

After that, the contact pressure decreases to the initial level, that is, the actual external surface of the retaining wall 1 caused the structure to work with constant resistance to shear forces, impending unstable slopes and slopes, as well as in undermined areas with horizontal and vertical movement of soil.

The current level of computers and software allows for accurate calculations of the stress state of fairly complex systems.

The use of modern programs oriented to the calculation of systems with a large number of unknowns is more efficient than calculations using traditional schemes.

According to some programs, it is possible to solve not only linear but also nonlinear problems.

In this case, consideration is given to the characteristics of the deformation of various materials: reinforced concrete, steel, base, etc.

To account for the work of the soil, several models have been developed that take into account the transition of the soil to a plastic state, viscoelastic deformation, and other models.

For each soil condition and type of stress state, it is advisable to select certain deformation models.

Of particular interest is the PLAXIS program for modelling contact interaction of elements of the “base – engineering structure” system [21, 22].

The PLAXIS program is a finite element package designed specifically for the analysis of the deformation and stability of geotechnical structures.

Modelling using the PLAXIS program made it possible to analyse the stress-strain state of retaining walls interacting with the soil mass in accordance with the design schemes for two options (Fig. 5): option I – corner retaining wall; II option – retaining wall with a structural surface. The simulation results are shown in Fig. 6–8.

As a result, a significantly smaller displacement in the retaining wall with a structural surface $U_{cm}=12.34 \times 10^{-3}$ m was obtained, but the entire soil mass with a more uniform distribution and reduced values was included on the contact surface σ_{ef} .

In order to determine the forces in the front and foundation plates, two variants of retaining walls were simulated using the “LIRA” program [23]. The design schemes are presented in Fig. 9. The calculations used the Mohr-Coulomb model.

Engineering-geological conditions and design loads are similar to previously performed calculations.

The first stage of the calculation was performed with a surface load $q = 49$ kN/m². The second stage of the calculation – with an additional vertical component for the front plate from the horizontal movement of the soil $q = 21$ kN/m².

The obtained values of bending moments in the front and foundation plates for two loads are presented in Fig. 10–12.

A new retaining wall structure with a structural surface was designed to secure the slopes of the Sushkov beam, the area of which is about 2 hectares (Fig. 13, 14).

The beam is located in the central old part of the city of Kryvyi Rih and was formed as a result of iron ore mining.

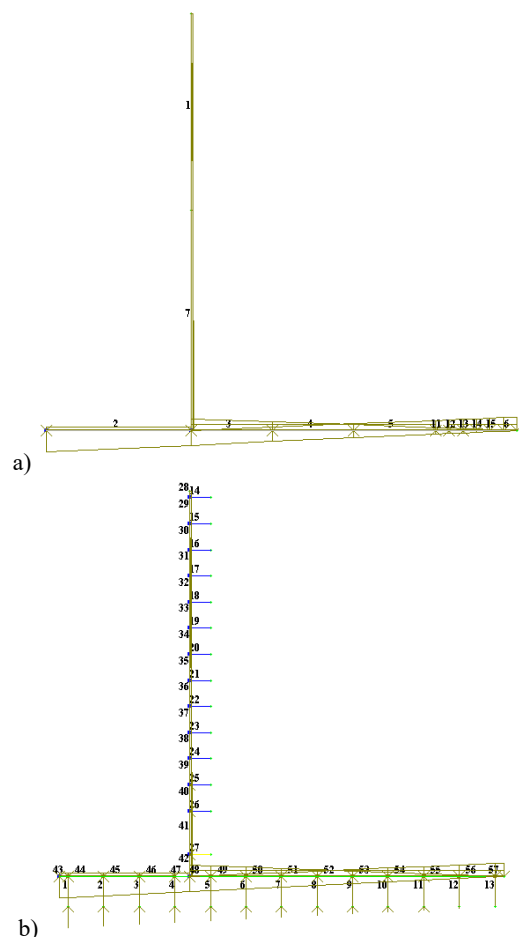

Fig. 9. Settlement schemes: a) I option; b) II option.

Fig. 10. Diagrams of bending moments: a) I option (first stage); b) II option (first stage).

Fig. 11. Diagrams of bending moments: a) I option (second stage); b) II option (second stage).

Fig. 12. Dependence of moments on surface load.

Over the past five years, engineering and geological conditions have worsened in the area of the beam: slope shifts in some places up to 12 cm, collapse of some slopes were observed, which in turn affected the normal operation of five-story residential buildings located at a distance of 8 m from the northern border of the beam.

The beam itself has slopes of 5 to 54% and is a dumping site for household waste.

In the geological structure of the site there are loams of the Quaternary sediment, clays, limestones under which the Precambrian clay shales are underlain. Groundwater is at a depth below 21 m.

The rational use of the territory was made possible only through the use of retaining walls with a structural surface.

They were installed around the perimeter of the site and diaphragm along the tiers.

The volumetric work of the retaining walls like the “egg’s volume” made it possible to include the entire soil mass around the beam, redistributing the contact forces in the best way, thereby reducing the maximum effective loads from the base.

A compact planning solution allowed in the extreme opposite points of the beam, where the greatest depth is located $-7.5 \text{ m} \div 8 \text{ m}$ (section 2-2, 7-7) place underground parking garages for 100 cars each. At the same time retaining walls simultaneously serve as walls of garages.

Above the underground garage are sports grounds for various sports with a modern bulk coating.

As mentioned above, the slopes of the beam are reinforced with monolithic reinforced concrete retaining walls, the height of which varies from 0.5 m to 3 m (section 1-1, 3-3, 4-4, 5-5, 6-6) depending on the existing depth beams, as well as their tiered device.

The rest of the territory is designed: a quiet recreation area, a children’s zone, a decorative zone, a walk-through zone, a public garden area.

5 Conclusions

The validity of the theoretical prediction of the engineering structures’ behavior interacting with unevenly deformed foundations cannot be obtained on the basis of the regulatory framework. This gap can be filled in when modeling the “base – engineering structure”

system using modern calculation programs using the finite element method.

The calculation results were confirmed by experimental studies conducted previously. Mathematical modeling made it possible to clearly demonstrate the decrease strain on the contact surface and in the body of the retaining wall with a structural surface with additional forces of soil displacement. The phased filling of voids

leads to a uniform distribution of deformations, in the long run increases the life of the structure, thereby ensuring an economic effect. The design feature of the retaining wall with the structural surface during soil interaction with it increases the bearing capacity of the base due to the joint work of the retaining wall structure and the deformable base.

Fig. 13. The plan of the retaining walls with a structural surface in the Sushkov beam.

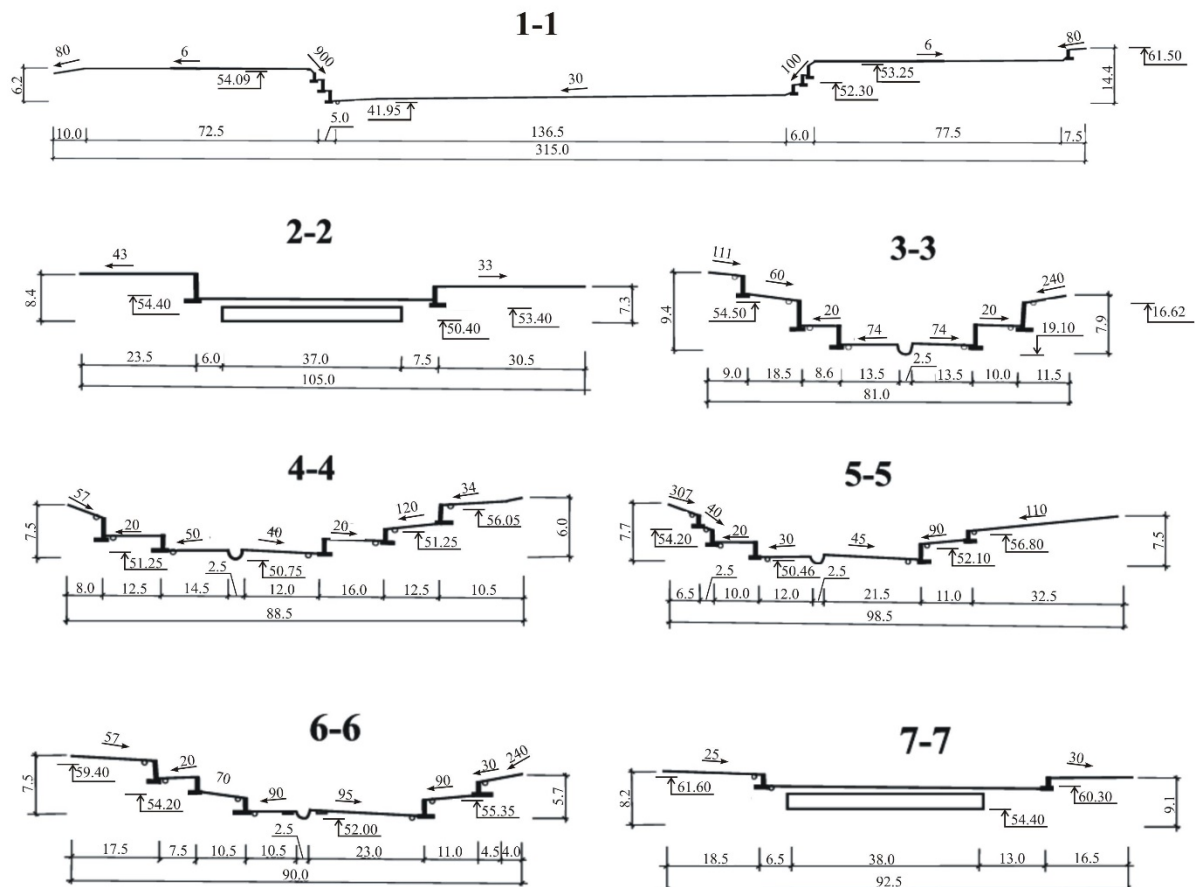

Fig. 14. Sections 1-1, 2-2, 3-3, 4-4, 5-5, 6-6, 7-7 along the Sushkov beam.

The proposed retaining wall can be used to stabilize unstable slopes and inclinations, as well as undermined territories of I, II, III, IV groups and subsidence soils.

The proposed retaining wall is characterized by high reliability of operation in a critical situation of unforeseen

emergency increase in horizontal and vertical power load. This is explained by the work of the structure itself, that is, with increasing load, the supporting areas of the prismatic sections increase all the time, and since the cavity volume sooner or later will be completely filled

with soil, then the supporting area of the retaining wall will increase significantly, and the average pressure will decrease when achieved degree of compaction. However, after this, the retaining wall will not be able to work in the mode of redistribution of contact pressures.

With possible vertical displacements of the soil, a constructive solution is also used that allows taking this type of deformation effects into account.

The use of previously unsuitable territory was made possible because of using retaining wall with a structural surface, which made it possible to obtain a significant economic effect due to a new design solution.

The use of this design for securing landslide slopes is advisable when erecting a height of up to 3 m, and the best work is achieved with a perimeter device.

Abstract. Further development of the open mining works on the domestic enterprises will be accompanied by the worsening of mining-geological conditions and declining of the quality of iron ore raw materials. In the same time, the accumulated mining wastes, that can make the technogenic deposits, pass into one of the important sources of the mineral raw materials. Taking into account this thing, the development and implementation of the modern technological circuits of the technogenic deposit development is an actual calling for mining industry, and determination and optimization of process conditions of the technogenic deposit development – is the scientific task of this publication. The obtained results of studies of the optimum step value of the ore chute transfer during the technogenic deposit development can be used by design organizations and mining enterprises for designing works. The obtained methodology and the proposed mathematical dependencies will reduce the cost of mining of the technogenic deposit due to the reasonable timely transfer of the open ore chute.

1 Introduction

As a result of activities of the mining and processing industry of the Kryvyi Rih region, hundreds of millions of cubic meters of production waste are accumulated on the surface in the form of overburden, sludge, slag, ash and so on, that increase the environmental load. More than 2 billion tons of rock mass is extracted annually from the Ukrainian subsoil, 60-70% of which is stored in the dumps. However, the level of utilization of production waste reaches only 12-15%, while in the advanced countries of the world it reaches 80%. The tendency for the use of secondary resources is observed in the USA, Japan, Canada, Great Britain, France, Germany, Republic of South Africa and other industrialized countries [1-4].

According to various estimates, up to 13 billion tons of overburden and up to 6 billion tons of washery refuses of low-grade iron ores are contained in the dumps and tailings ponds of Kryvyi Rih mining and processing enterprises. At the same time annual economic damage from environmental pollution is estimated at \$300 million. However, the prospects for the development of mining are characterized by an increase of the mineral output with a constant decrease in their quality and complication of the conditions of exploitation of natural deposits. In future, deposits of low quality ores, comparable to the ores of technogenic deposits, will be involved in the development.

The amount of mineral resources contained in mining waste is anthropogenic raw material, the involvement of which in the processing will reduce the cost of

exploration for new and mining of exploited deposits, release land occupied waste and their reclamation, elimination of sources of pollution from the surrounding environment around operating enterprises [5].

Thus, anthropogenic formations formed by the storage of mining and processing waste, provided the required quantity and quality of mineral raw materials, can be suitable for industrial use and as a result can be considered as technogenic deposits.

By definition of V. O. Gneushev [6], man-made mineral deposits are places of accumulation of mineral extraction and processing of mineral resources whose reserves are estimated and have industrial significance. Like natural mineral deposits, such deposits have a certain structure spreading of useful components, the zone of secondary enrichment and oxidation.

It is established that the deposits that are mined in 40th – 50th of 20 century, accumulated a significant amount of technogenic waste with relatively high content of useful components, because at that time the extraction and processing conditions were much higher than today [7].

Dumps of Kryvyi Rih mining enterprises are made up of overburden rocks that have been removed from the subsoil, moved and stacked. Their mineral and chemical composition, texture, structure, physical, technological, technical and other characteristics have practically not changed in comparison with the corresponding parameters of these rocks in the geogenic deposit.

Thus, the accumulated mining waste, which may be technogenic deposits, will eventually become one of the important sources of mineral resources. In view of this,

* Corresponding author: Juliangrig@gmail.com

the problem of development and improvement of formation and mining technologies of technogenic deposit with optimal parameters that would ensure maximum efficiency of its development is especially up-to-date and needs further research.

2 Materials and methods

V. D. Evtekhov [8] claims that the technogenic deposits represented by the waste heaps of mining enterprises have been studied more deeply to date, and the first steps have been taken in the direction of their industrial exploitation. For some rocks extracted from the depths along with iron ores, and for some areas of their application, the problem of recycling can be considered theoretically and practically solved.

For example, the production of rubble stone, ballast raw materials, as well as materials for road construction of granitoids, substandard magnetite-silicate quartzites and different composition of shale.

Undoubtedly, the development of bulk man-made deposits would be economically feasible. This is due to the fact that the cost of finished products from man-made raw materials is lower than the primary cost of raw materials extracted from the subsoil.

In addition, the terms of development of technogenic deposits from exploration to production of the finished product is much less than in geogenic one.

In order to bring the technogenic deposit into operation, it is necessary to solve a complex problem, which includes a number of issues, such as determining the mineralogical composition of the technogenic deposit, its area and capacity, the content of the useful component, the particle size spreading; identifying the most promising areas; collecting data on the spatial spreading of pollution in man-made sediments; estimated calculation of inventories of useful components, as well as a plan of development taking into account technological types of shifts and compilation of geological map and sections [9]. However, the haphazard storage of rocks in the dumps leads to complications in their development as man-made deposits, which is explained by the higher costs of performing the required amount of mining work on the extraction of mineral resources.

V. V. Kustov proposes [10] to use the phenomenon of segregation, which is the process of separation of bulk material by size as a result of interaction between particles of bulk material and additional external factors, to predict the parameters and qualitative assessment of the massif of rocks of technogenic deposits. The author notes that the effect of segregation is occurs in the dumping of waste rocks, and therefore it is important to know the regularities of segregation processes in determining technological schemes of repeated impact on the dumps, in solving problems of engaging in the production of technogenic deposits with certain zones of concentration of useful component of the bulk and prediction of objects. Therefore, according to the author, one of the main criteria when choosing a rational technology for the formation of anthropogenic deposit is

the degree of segregation of bulk rock, which will allow to form an technogenic deposit with the necessary parameters that would provide a given quality of mineral raw materials.

On this basis, Kustov developed 11 technological schemes for the use of dump equipment for the formation of technogenic deposits of layered structure, which would provide the maximum degree of segregation of bulk rocks with the purpose of maximum material disclosure in size.

The developed technological schemes involve the use of conveyor or wheel transport and are distinguished by the technological operations performed. The most effective technological schemes in terms of qualitative separation of loose rocks into fractions are schemes with conveyor dumping and in the case of dump trucks for peripheral dumping.

The group of scientists of IGTМ NAS of Ukraine under the leadership of M. S. Chetverik productively explored the problem of the technology of technogenic deposits' development [11], but mainly deposition of shore type, that significantly narrows the scope of the results.

A team of scientists from Kazakhstan led by Ye. I. Rogov investigates the development of technogenic deposits of bulk type, but with the use of leaching [12]. However, this technology cannot be effectively applied for the Kryvyi Rih iron-ore deposits. In addition, its application will increase the environmental load to the region.

Well known the schemes of selective storage of rocks in waste dumps: storage of each separate type of raw material on its own, separated in parts of surface area; storing different types of raw materials in one plot with their distribution in plan; storage of different types of raw materials in one section with their height distribution; storage by a combination of the second and third methods. Storage by the first method is in fact a common dumping. Selective storage with height distribution of raw materials is possible when the prospective value of the ores is clearly defined. At the same time, the least valuable ores should be at the base of the rock mass and deep into its side parts, and the most valuable ones should be at the upper tiers of the technogenic deposit. The most valuable fraction will be concentrating on the outer sides of the rock mass, so its subsequent shipment will not cause any inconvenience. However, over time, the importance of certain types of minerals may change, so the current storage system in the future may interfere with access to the mineral component.

In this way, the most selective warehousing technologies provide for the opening of a deposit only after its backfilling by passing the surface trenches [13-15]. Technology for the formation of technogenic deposits with the establishment of tunnels system and ore pass, described in the investigation [16] has fundamentally difference from the described ones.

This technology involves the discovery of a bulk technogenic deposit as an object of development, still in the formation stage. The developed technology allows to reduce the costs for development of the technogenic

deposit and to increase the completeness of the mineral's extraction by simplifying the access of extractive equipment to the mineral. Despite this, this technology has several disadvantages:

- the formation and processing of technogenic deposits in this way involves significant capital expenditures during the building phase. At the same time, 17% of them are the cost of laying the fastening system, which is explained by the complexity of the installation work and the high cost of the used materials;
- fastening system that is in the thickness of the technogenic field, especially horizontal tunnels, require periodic metrological control, because they are in a constantly tense state;
- the installation of the vertical fastening system requires only a bulldozer peripheral method of dumping. It is characterized by an almost uniform distribution of oversize over the thickness of the technogenic deposit;
- in this technological scheme with the placement of vibratory feeders at the bottom of the vertical cavities, is possible emergency stop of work due to oversize of rock. Therefore, the proposed technological scheme requires a uniform particle size distribution without oversize.

The technology of the technogenic deposit development with open ore chutes is free of the above mentioned disadvantages. In this case the formation of the technogenic deposit is performed by known storage technologies, and after the backfilling of the technogenic deposit or if a certain slope enters on the designed contour, a mobile or stationary ore chute in the form of an open trench can be formed on it. A transfer bin equipped with a vibrating feeder is placed at the bottom of the ore chute. The method of the technogenic deposit development is as follows: the wheel loader removes the minerals from the face and transports it to the accumulating tank, from where it is delivered over the open ore chute to the vibrating feeder under the action of gravitational forces and transferred to the means of railway transport. Choosing the location of the technological complex we should take into account the effective distance of transportation of the wheel loader, that is limited to 500 m. However, this publication does not consider the choice of the direction of development of mining works from the receiving tank of the vibrating feeder, the optimal values of the width of the work stope and other parameters of the elements of the development system.

At the same time, the development of the technogenic deposits of the bulk type according to this technology is an imperfect and is characterized by low technical, economic and technological indicators, which keep its further introduction. This situation can be corrected by identifying and optimizing the parameters of the elements of the technogenic deposit development system, as well as further improving existing technologies by increasing the efficiency of equipment use.

3 Results and discussion

For a detailed study and further research of the

technological scheme was first investigated range of pneumatic wheel loaders. It was considered five pneumatic wheel loaders on the example of the model range of the "Caterpillar" company. First of all, the technical parameters of the CAT-962L, CAT-966L, CAT-980H, CAT-992K, CAT-993K machines were analyzed [17], and then their productivities were calculated for the conditions of technogenic deposits.

For these conditions capital and operating expense for mining of technogenic deposit with each loader were calculated. For the accuracy of the results, calculations were made for transport distances of 100 m, 200 m, 300 m, 400 m and 500 m. The results of these calculations of capital and operating expense per 1 m³ of the rock are shown in table 1.

Table 1. Calculation of total CAPEX and OPEX for the different pneumatic wheel loader, USD per 1 m³

L, m \ E, m^3	4,4	7,4	8,2	12,3	23,7
100	0,07	0,05	0,06	0,25	0,21
200	0,11	0,09	0,11	0,48	0,34
300	0,11	0,09	0,11	0,48	0,34
400	0,23	0,17	0,21	0,86	0,71
500	0,29	0,21	0,28	1,15	0,86

Consideration of the proposed examples of equipment from the point of view of economic feasibility, performance or combination of these components will indicate the absolute inappropriateness of the application of the CAT-992K brand with a bucket volume of 12,3 m³, since this sample cannot compete with any of the presented models, having high specific indicators costs at relatively low productivity.

The results obtained allow us to conclude on the economic feasibility of using pneumatic wheel loaders CAT-962L, CAT-966L, CAT-980H for mining of technogenic deposits with open ore chute. The results are shown in fig. 1.

Fig. 1. Dynamics of mining costs for loaders with different buckets (E) depending on the distance of transportation.

But for the further research we will select loader

CAT-966L, which has the best technical and economic indicators.

Obviously, in order to maximize the productivity of the loader, which operates according to the technological scheme with open ore chute, the distance of transportation of technogenic raw materials should be minimal. Such condition will be fulfilled, developing the massif by radial slicing, as shown in fig. 2. The essence of technology is as follows.

Fig. 2. Scheme of development of the technogenic deposit by radial slicing with pneumatic wheel loader: 1 – open ore chute; 2 – pneumatic wheel loader; 3 – axis of a railway transport; 4 – radial slicing.

The loader begins to develop the deposit directly near the ore chute at the shortest transport distance, thus forming a radial slicing. After that, it comes to the next slice with a larger radius and so on. The extension of the radius continues until the transport length reaches the limit, which is usually assumed 500 m for wheel loaders. The aim of the proposed technology is in the constant minimization of the transportation distance of the mining mass from the face to the receiving tank of the open ore chute. So, we transfer the development of the mineral, which is to be transported to a larger distance, to the later period. As a result, discounted costs for the transportation also diminish.

Let's make a model of mining works on the technogenic deposit. The following mathematics calculation will be done for these purposes. The volume of the first slice will be calculated from the elementary formula of a half of an area of a circle $V=0,5\pi L^2 h_s$.

Now we will calculate the volume of every following slice according to the formula (1):

$$V = \frac{\pi(L^2 - l^2)h_s}{2}, \quad (1)$$

where L – radius of a current radial slice, m

l – radius of a previous radial slice, m

h_s – high level of a stage of the technogenic deposit, m

At the same time the volume of a slice is equal to the product of the loader's productivity to the time of the

development. On the base of preliminary calculations, we can determine the time of the slice development according to the formula (2):

$$t = \frac{\pi h_s (L^2 - l^2)}{2 Q_{pn}}, \quad (2)$$

where Q_{pn} – productivity of a wheel loader, m³/t.

For the conditions of using the pneumatic wheel loader CAT-966L with the height of a stage 12 m we will make calculations for different transportation distances from 10 to 500 m with the step 10 m and tabulate the results in table 2.

Table 2. Calculation of working time of radial slicing for the pneumatic wheel loader

L, m	Q_{pn} , m ³ /sh	Cumulative working time, sh	Time of radial slicing working, sh	Volume of radial slicing, m ³
10	20753,1	0,1	0,1	1885,0
20	18078,5	0,4	0,3	5654,9
30	16014,6	1,0	0,6	9424,8
40	14373,6	1,9	0,9	13194,7
50	13037,7	3,2	1,3	16964,6
...
470	2658,8	1115,8	65,9	175300,9
480	2609,3	1184,4	68,6	179070,8
490	2561,7	1255,8	71,4	182840,7
500	2515,7	1330,0	74,2	186610,6

On the basis of the received data, we can make a diagram of dependence of the transportation distance on the time, which was taken for the development of the radial slicing (Fig. 3).

Fig. 3. The dependence of the transportation distance by the radial slicing on the time of the development.

This dependence can be described by the equation of the exponential function $L=32,648t^{0,3792}$. The obtained diagram allows approximately determine the rate of movement of mining works at the technogenic deposit and dynamically plan mining works on different stages.

On the one side, the proposed technology of development by radial slicing transfer transportation expenses to the later period, but afterwards it will require additional units of mining and transport equipment.

Calculations, performed in the previous sections, allowed to make a conclusion that the productivity of the loader will reduce while removing the face from the ore chute. This clearly shows the diagram of the loader productivity on the radius of the radial slicing (fig. 4).

Fig. 4. The dependence of the shift capacity of the loader on the working time with increasing radial slicing radius.

As a result of the conducted researches there was an idea to reduce transportation distance by transferring the open ore chute. It will provide the rise in productivity and, consequently, will diminish the equipment stock and the development period of the technogenic deposit. During the periods of increasing transportation distance,

the transfer of the ore chutes will allow to keep the equipment stock at a constant level.

However, there is a question of the step of its reinstalling. On the one side, an insufficient transfer step will result in a higher cost of dismantling and installation of the ore chute and the vibrating feeder. On the other side, the work with a long transportation distances increases operating costs.

So, the rational value of the transfer step should be determined by the economic criteria.

We describe mathematically the necessary condition of equality by the formula (3).

$$C \times t + EK = C \times (t - \Delta t) + EK + \Delta C, \quad (3)$$

where C – specific operating costs for the loaders, ore chutes and feeders, USD/shift;

ΔC – additional operating costs for dismantling/installation of vibrating feeders and ore chutes, USD;

K – capital expenditures for loaders, ore chutes and feeders, USD;

t – time of working of the radial slicing according to the basic variant, shifts;

Δt – change (reduction) of working time due to the transfer of ore chutes, shifts;

E – norm. coefficient of reduction of capital expenditures.

Fig. 5. Scheme of development of the technogenic deposit with reinstalling of the open ore chute: 1 – open ore chute in new in the current position; 2 – pneumatic wheel loader; 3 – radial slicing; 4 – axis of a railway transport; 5 – radial slicing for old open ore chute position; 6 – open ore chute in the old position; S – step of reinstalling of the open ore chute.

Let's simplify the expression, change the working time with respect to the volume change to productivity, which in turn also depends on the transportation distance and time, take into account the system of restrictions and obtain a mathematical model for the technogenic deposit in 2 stages and get formula (4):

$$\sum C \frac{\pi(L_i^2 - L_{i-1}^2)h_s}{2Q(t)_i} - \Delta C \rightarrow \min \quad (4)$$

$$\begin{cases} L_i \geq L_{i-1} \\ h_s = [8; 15], \end{cases}$$

where i – optimization is completed according to the number of radial slicing, every increasing i corresponds to the increase of the radius on 10 m.

Search of the optimal value of the transportation distance will be performed in MS Excel using the reduced gradient method. For the technogenic deposit in 2 stages with a height of a stage 12 m and a loader with a bucket capacity of 7.4 m³, the maximum economically feasible transportation distance, which corresponds to the radius of the radial slicing, will be 183 m.

So, the scheme of development of the technogenic deposit with reinstalling of the open ore chute is given in the fig. 5.

However, it is obvious that the obtained result of the optimum transport distance should also be verified by the technological criterion, namely: the weighted average performance of the pneumatic wheel loader is to correspond to the performance of the vibrating feeder, as otherwise there will be technological downtime. In our case, the weighted average capacity of the loader is 7686 m³/shift, and the vibration feeder is 7680 m³/shift, which corresponds to the condition of equality. Thus, according to fig. 4, for these conditions, the step of reinstalling of the open ore chute S between axes of open ore chutes for the new and old positions will be equal 366 m as two radii of radial slicing.

4. Conclusions

The obtained model allows to minimize the cost for development of the technogenic deposit due to the reasonable timely transfer of the ore chute and productivity increase of the wheel loader. The obtained dependences allow to plan the dynamics of development of the mining front at the technogenic deposit.

Further studies will focus on identifying and optimizing other parameters of the elements of the development system and creating a classification for the development systems of technogenic deposits.

Abstract. The economic efficiency of the enterprise and the length of its operation, the full utilization of mineral reserves and the total cost of operation depend on the selected depth and boundaries of opencast mining. In such conditions of the deposits' development it is necessary to evaluate the capabilities of the raw material base for the further development of the mining enterprise. The basis for determining of the border overburden ratio is on the condition that the price of manufactured marketable output of the designed enterprise should not exceed the price of the same marketable output in the world market. The realization of this condition is achieved analytically. This takes into account the impact of the rate of return on the final depth of the designed open pit. A new method of determining of the border overburden ratio is developed, which ensures the competitiveness of iron ore concentrate in the world market. The value of the border overburden ratio is developed for the Pershotravneviy open pit of the Northern mining and processing plant, depending on the situation of the iron-containing products' prices, which ensures the competitiveness of marketable iron-ore output in the domestic and world markets.

1 Introduction

The economic efficiency of the enterprise and the operation period, the full utilization of mineral reserves and the total cost of operation depend on the selected depth and boundaries of the opencast mining.

Nowadays, in the development of steeply falling iron ore deposits, their working contours on the surface have reached design marks on the most open pits. Mining development occurs only when they are lowered. In such conditions of the deposit development it is necessary to evaluate the capabilities of the raw material base for the further development of the mining enterprise.

When choosing opencast mining alternatives, their main parameters – open pit boundaries, mining mode and ore productivity – are assessed by economic indicators. These indicators are: profit from sales of saleable output; production costs of the saleable output; profitability, etc.

As practice shows, the depth and position of the final boundaries of the most large open pits as the mineral deposits are worked out are repeatedly revised and adjusted. However, it is imperative to determine the final boundaries of the open pit mining in which the development of open pit deposits will be effective. There is a concern about the designing a new enterprise, when similar mining companies are already operating.

Recent applied and scientific studies on this issue clearly indicate the need to re-evaluate the final boundaries of Ukraine's open pits [1-3]. The development in the approved by existing designs boundaries can lead

to the rapid depreciation of the loading faces of the open pits on the final designed boundaries in the near future. And this will entail a significant increase in the cost of the opencast mining due to the reactivation of non-working faces, if the open-pit boundary will be redefined in future.

At present, there are a lot of methods in the theory and practice of design to determine the border overburden ratio and open-pit boundaries that develop steep-dipping banks. Today, the open pit boundaries are determined on the basis of a comparison of one of the overburden ratio of the designed open pit with the border overburden ratio. At the same time, to determine the border overburden ratio, economic indicators of the cost of ore underground mining method or the wholesale price of the mineral are most often used. However, in the world market of commodity iron ore products the only indicator of its competitiveness is price. Production costs and profitability are commercial secret. Therefore, the main condition for a comparative assessment of the operational efficiency of mining and processing plant in the world market is to compare the price of marketable products with the price of the same marketable products in the world market.

2 Object and methods of research

A great number of scientists were engaged in the questions of determining the open pit boundaries. The largest contribution [4-11] in the theory of designing the boundaries of open-cast mining is owned by

* Corresponding author: julianrig@gmail.com

A. I. Arsenyev, V. V. Rzhetskij, B. P. Yumatov, V. S. Hohryakov, V. G. Bliznyukov, A. K. Polishuk, Yu. I. Anistratov.

Designers and scientists use the main criteria for evaluating [9-10] the boundaries of effective mining of open-pit deposits use the cut-off (economically viable) overburden ratio as the main criterion, which is the maximum permissible overburden ratio, according to which open-pit mining in these specific conditions economically feasible.

There are several well-known principles to justify the depth of the open pits, based on the comparison of one of the overburden ratio (average, initial, contour, current, mid-operational) or the sum of these coefficients with the cut-off (economically feasible) overburden ratio.

The economic basis of all calculation principles for determining the boundaries of the open pits is to compare the possible cost of ore mining with the expected over the designed open pit [12], and the cut-off overburden ratio of the overburden is calculated by the technical and economic indicators achieved at the mining enterprises at the time of design.

In this case, to determine the cut-off overburden ratio, the most commonly used economic indicators of the cost of ore mining by underground method or the wholesale price of minerals.

However, it should be understood that comparing the cost of open and underground mining is not correct due to the different production volumes; the open pit productivity is much higher than the productivity of mines, which to a different extent covers the needs of the market. In addition, the cost of mining by underground method remains equally high throughout all the service life, while the open pit reaches a production cost peak in only one of the operating periods at which the surface boundaries reach the final pit.

Recently, studies have been conducted on the determination of prospective mining boundaries of the open pits: the Scientific and Research Mining Institute (SRMI) [1, 13]; The Academy of Mining Sciences of Ukraine [2] and Kryvyi Rih National University (KNU) [3]. The determination of the cut-off overburden ratio was performed by these institutes on the basis of comparison of indicators of work of the investigated enterprise with indicators of enterprises with the underground method of mining, as well as with indicators of similar mining and processing plants. The price of the marketable products (concentrate), which depends on its quality, has always determined the boundaries of opencast mining. However, at different mining enterprises, marketable products of the same quality may have different selling prices [14], which in turn may make an error in determining the final boundaries of the open pits. Therefore, in the paper [15] it was proved contractual factors influence on the price of commodity products, which makes inaccurate application of existing methods for determining the final open pit boundaries.

However, the existing methods of determining the cut-off overburden ratio [16-18] do not take into account the competitiveness of the iron ore products of the designed enterprise in the world market.

At present, the strategic assessment of the interaction of the company with the external environment we must first take into account the qualitative and quantitative impact of competitors and demand on pricing [19], and, accordingly, the profit of the enterprise [20]. With different levels of the competitive environment and the supply-demand relationship, different options for choosing mining company strategy and, accordingly, a suitable methodology for selecting the final open pit outline.

Therefore, the goal was to develop a method of determining the cut off overburden ratio, which will allow while the formation of the price for iron ore products on the world market to determine the boundaries of the open pit, that ensures the competitiveness of mining and processing plant.

To achieve this goal, a complex research method was used in the work, which includes theoretical and instrumental methods: analysis and theoretical generalization of enterprises reports, scientific and technical publications and other information sources in the field of determining the boundaries of careers in substantiating the problem and task of research; system analysis in researching career indicators; analytical, graphical and graphoanalytical methods of the research of technological and economic interconnections of the mining mode and the productivity by minerals in determining the boundaries of the career; economic and mathematical modeling of career options.

3 Results

The only indicator of the competitiveness of the marketable iron ore products is its price. Therefore, the main condition for a comparative assessment of the designed mining and processing plant in the world market is to compare the price of finished product with the price of the same product in the world market. Hence, the basis of the determination of the cut-off overburden ratio will be the condition that the price of the finished product of the designed enterprise does not exceed the prices of the same marketable products in the world market, which is represented by inequality:

$$P_c^d \leq P_c^w \quad (1)$$

where P_c^d – the price of the concentrate of the designed mining and processing plant, UAH/t; P_c^w the price of the concentrate in the world market, UAH/t.

At any mining enterprise we plan the profit margin, which is expressed by the final sum of production profitability of the enterprise. Therefore, the price of the concentrate of the designed mining and processing plant can be represented as:

$$P_c^d = C_c^d \cdot (1 + \psi), \text{ UAH/t}, \quad (2)$$

where C_c^d – the prime cost of the concentrate of the designed mining and processing plant, UAH/t; ψ – target profit margin, parts un.

The cost of production of the concentrate of the designed mining and processing plant will be represented by the expression:

$$C_c^d = \frac{a_m^d + a_c^d + b^d \cdot n}{\gamma_c^d}, \text{ UAH/t}, \quad (3)$$

where a_m^d – the cost of ore mining without the expense of the overburden in the designed open pit, UAH/t; a_c^d – the cost of the ore conversion to the concentrate at the designed mining and processing plant, UAH/t; b^d – the cost of the overburden in the designed open pit, UAH/m³; n – the overburden ratio in the designed open pit, m³/t; γ_c^d – concentrate output from one ton of ore to the designed mining and processing plant, parts un.

On this basis, the expression of determination of the concentrate price of the designed mining and processing plant (2) will take the following form:

$$P_c^d = \frac{a_m^d + a_c^d + b^d \cdot n}{\gamma_c^d} \cdot (1 + \psi), \text{ UAH/t}. \quad (4)$$

The price of concentrate, which is on the world market, depends on the content of iron. Therefore, the price of the concentrate of the designed mining and processing plant should be brought (in terms of the content of iron) to the price of the base enterprise (the price of concentrate and its iron content in the world market). Then the expression will look like this [1]:

$$P_c^d = P_c^W \cdot \frac{\beta^d}{\beta^W}, \quad (5)$$

where P_c^d – the present value of the concentrate of the designed mining and processing plant at the price of concentrate and the content of iron in it on the world market, UAH/t; β^W i β^d – iron content in the concentrate in the world market and designed mining and processing plant, accordingly, parts un.

On this basis, the price of the designed concentrate will be defined as:

$$P_c^d = \frac{\beta^d \cdot (a_m^d + a_c^d + b^d \cdot n)}{\gamma_c^d \cdot \beta^W} \cdot (1 + \psi), \text{ UAH/t}. \quad (6)$$

Based on formula (2), the cost of concentrate on the designed mining and processing plant as an indicator of competitiveness, depends on the planned profit and volume of overburden works. Other indicators are determined by the level of technology and technology of ore and dead rocks mining (a_m^d i b^d), achieved at the enterprise, indicators of technology for ore conversion to concentrate and quality of ore (a_c^d , γ_c^d , β^d).

These indicators in determining the competitiveness of similar companies, can be taken constant, as they do not change for a long time, and if they change, then at almost the same rate. For example, let's consider the graphs of the change in the price of concentrate of the North mining and processing plant from the current overburden ratio with different iron content in concentrate in the world market (Fig. 1, 2).

From the presented pictures we can see that while maintaining the profitability of the enterprise at the same level, with the increase of the overburden ratio, the price

of production should increase. With a constant overburden ratio, increasing profitability is possible only with the increase of the price of products.

Fig. 1. Changes in the price of the concentrate of the Northern mining and processing plant, depending on the current overburden ratio when the iron content of the concentrate in the world market 65%: 1 – at the rate of profit $\psi = 0\%$; 2 – when $\psi = 30$; 3 – when $\psi = 50$.

Fig. 2. Changes in the price of the concentrate of the Northern mining and processing plant, depending on the current overburden ratio when the iron content of the concentrate in the world market 66%: 1 – at the rate of the profit $\psi = 0\%$; 2 – when $\psi = 30$; 3 – when $\psi = 50$.

Thus, with the increase of the overburden ratio and with the increase of the profitability of the enterprise, the price of production of the designed enterprise will increase. There will come a time when the price of production will rise to the limit value P_c^W . Then, substituting in the condition of competitiveness of marketable product of the designed pit (1), the value of its possible price, we obtain:

$$\frac{\beta^d \cdot (a_m^d + a_c^d + b^d \cdot n_{c.o.}) \cdot (1 + \psi)}{\gamma_c^d \cdot \beta^W} \leq P_c^W. \quad (7)$$

Based on this inequality, the cut-off overburden ratio is defined as:

$$n_{c.o.} = \frac{\frac{p_c^W \cdot \gamma_c^d \cdot \beta^W}{\beta^d \cdot (1+\psi)} - (a_m^d + a_c^d)}{b^d} \quad (8)$$

In the table 1 we report the present value of the concentrate of the Northern mining and processing plant calculated by the formula 6.

Table 1. The price of concentrate on the world market and the price of the concentrate of the Northern mining and processing plant depending from the iron content.

Iron content in the concentrate, %	The price of the concentrate, UAH/t	
	In the world market	Discounted value Northern MPP
62	1086,4	1150,2
63	1127,0	1174,2
64	1167,2	1197,1
65	1208,0	1219,9
66	1248,0	1241,2

Substituting the value of economic and technological indicators of the Northern mining and processing plant in expression (8), we determine the cut-off overburden ratio with different values of profitability (profit rate: 1 – 0%; 2 – 10%; 3 – 20%; 4 – 30 %; 5 – 40%; 6 – 50%). This is shown in Fig. 3. The points in the Fig. 3 correspond to the iron content of the concentrate on the world market.

Fig. 3. The dependence of the cut-off overburden ratio on the price of concentrate in the world market: 1 – at the profit rate $\psi = 0\%$; 2 – with $\psi = 10\%$; 3 – with $\psi = 20\%$; 4 – with $\psi = 30\%$; 5 – with $\psi = 40\%$; 6 – with $\psi = 50\%$.

In Fig. 4 we present the dependence of overburden ratio from the profit rate for the working conditions of the Pershotravnevij open pit of the Northern MPP.

For example, it is necessary to find out what the price of a concentrate with an iron content of 65.5% at a rate of 40% will be. To do this, on the curve with the required norm of the profit (curve 5, Fig. 3) we find a given value of iron content. From the value of the desired iron content (between the group of vertical points 65% and 66%), lower the perpendicular (dashed lines, Fig. 3) on the y-axis and abscissa and determine the values of the overburden ratio and the concentrate price. That is, with

an iron content of 65.5% and a profit rate of 40%, the overburden ratio will be 4.8 m³/t, and the price of concentrate – 1228 UAH/t.

Fig. 4. The dependence of the cut off overburden ratio on the profit rate for the working conditions of the Pershotravnevij open pit of the Northern mining and processing plant.

Studies on theoretical open pits and powerful iron ore open pits of Kryvbas have shown that the accuracy in determining of the open pit boundaries that do not take into account market conditions is up to 50%. Thus, it was determined that in order to more accurately determine the open pit boundaries, it is not necessary to take into account the levels of competition, supply and demand. However, in light of the fact, that it is difficult to predict economic indicators with a high degree of accuracy, it is necessary to move from difficult-to-predicted economic indicators to more stable technological ones when determining the pit outline.

Such technological indicators may serve changes of the ore volumes and overburdens in open pits-competitions.

In this regard, before designing it is important to carry out analytical work, to make forecasts about the future conditions of competition and demand, as well as changes in price trends and cost of marketable product. At the design stage, it is important to work out the most likely scenarios, and the economic effectiveness of the variants of the final pit boundaries must be determined taking into account the risks of the probably change in the market conditions.

4 Conclusions

A new method of determination of the cut-off overburden ratio has been developed, that allows the determining while the world market price of iron ore products to determine the open pit boundaries, which ensure the competitiveness of mining and processing plant. According to the developed method, the values of the cut off overburden ratio for the Pershotravnevij open pit of the Northern mining and processing plant were determined, which ensure the competitiveness of iron ore

marketable product in the world market at different values of the profit rate. Thus, this principle of defining the boundaries of opencast mining takes into account the dynamics of the external competitive environment of the mining enterprise.

Abstract. The article aims to develop the resource-saving technology when mining steep ore bodies applying 250 mm-diameter boreholes to break ore into the compressed environment. This will reduce dilution of the mined ore mass in conditions of rock pressure around blocks. When mining iron ore deposits of Kryvyi Rih basin, applied mining systems allow for creation of the compensatory space as the first stage. However, these stopes fail under rock pressure, this influencing negatively ore breaking and extraction. The degree of extraction can be increased through breaking ore mass into the compressed environment. The width of the ore layer to be broken onto the compressed environment is determined through industrial investigations. To enhance breaking conditions, it is suggested to apply boreholes of a larger diameter. However, there is no technique developed for determining thickness of the ore layer to be broken depending on the borehole diameter and the fragmentation factor. When applying 250 mm boreholes, increase of thickness of the layer to be broken from 2 to 10 m is found to cause compaction of the previously broken layer up to 3 m with the optimal ore fragmentation factor of 1.3–1.5 and 3-fold decrease of lumps yield. This results from the fact that drilling a 250 mm borehole to secure even provision of the massif with explosives reduces the line of the least resistance.

1 Introduction

Kryvyi Rih iron ore basin accounts for over 32.2 bn t of iron ores with iron content in the massif of 24–65% that are mined by underground and open-pit methods. Iron ores with the useful component content of 60–65% are mined applying bulk-caving methods on the compensatory area or open stoping and further caving of enclosing rocks [1–4].

Underground mining of ore bodies is performed at the depths of 1220–1350 m. Geometric parameters of ore bodies are as follows: along the strike length is 800–1200 m; thickness is 30–120 m; dip angles are 45–85° [5–7].

Mining operations are performed in the following order: the ore body is vertically divided into levels of 75–90 m high; it is mined along the strike from the center to its flanks or from the flanks to the center. Nevertheless, because preparation operations are behind schedule, mining enterprises do not keep to this order that results in concentration of stresses around the block and decreased ore extraction [8–10].

Works [11–15] suggest various options of mining systems enabling increase of extraction of ore mass from stope blocks. However, blocks fail under the influence of rock pressure when forming the compensatory area, thus causing increased mining costs and time.

To increase iron content in the muck, it is suggested to concentrate the mass at surface crushing and sizing plants. [16–18]. It should be considered that in terms of mineralogical composition there are 6–9 varieties of ore, each requiring special treatment. At present, there are developed and successfully implemented various automated complexes due to which the useful component content in ore mass increases by 3–6% (i.e. from 56% to 62%) [19–21]. This updating trend is based on force impacts on the substance during disintegration in the activator but it does not consider processes connected with underground mining of the useful mineral [22–25]. Constantly improved software of the automated complexes indicates iron content in real time and is able to split ore mass flows by quality.

Nevertheless, all these measures inevitably result in increased mining costs (by 2–7%), decreased annual output of the mine (by 10–20%) and alienation of agricultural lands for external dumps.

Therefore, to decrease mining costs, a technology should be developed to mine blocks in complicated mining and geological conditions without increase of mining costs.

For successful mining of blocks with unfavourable conditions around them, it is reasonable to apply bulk-caving systems without creating significant exposures. Such system is used at Kiruna mine (Sweden) [26–28].

* Corresponding author: psvknu@gmail.com

The point of the system is in the decreased sublevel height and borehole breaking onto the compressed environment with end drawing due to which the amount of pure undiluted ore mass mined increases [29-32]. However, a considerable number of haulage workings require additional expenses.

When implementing this technology at underground mines of Kryvyi Rih iron ore basin, labour conditions deteriorate and costs for maintaining workings grow because of complicated mining and technical conditions [33-36].

To reduce costs for maintaining main openings, mines implement modern methods of monitoring the rock massif state while disturbing it by underground operations [37-39].

It is also possible to reduce costs on maintaining workings at the expense of breaking ore by deep boreholes onto the compressed environment.

When breaking ore on the compressed environment, the surface of the working is in direct contact with the rock massif and, therefore, the elastic wave from one environment moves into another, into the incident energy. Reaching the fragmentation factor ($K_f = 1.3 - 1.4$), part of the direct energy is used to destroy the rock massif (75 – 90%), and part (10 – 25%) - to compact the material. Displacement of the compressed material in the stope occurs after blasting of the first ring of holes and reaches 3 m at 4–5 row blasting (or blasting 3 rows of parallel contiguous borehole rounds) and then stops. Material compaction occurs within the 25 – 30 m wide area if ore hardness is average and does not exceed 15 m if rocks are hard [40,41].

Partial drawing of caved ore creates necessary loosening of rock mass before breaking. The number of rows for blasting should be sufficient for the material not to be excessively compacted.

However, application of borehole breaking with the diameter of holes of 105 mm increases expenses on drilling as the number of borehole rings increases 2–3-fold.

2 Methods

Based on the conducted critical analysis of works dealing with issues of increasing ore mass extraction in conditions of rock pressure around blocks, the following conclusions can be drawn:

1. The authors suggest increasing the iron content in ore mass at the expense of a mining and concentrating complex or through applying the selective energy saving technology aimed at excluding the concentration process or creation of the compensatory area of various shapes. This will unavoidably result in increased mining costs and, consequently, loss of the world market.

2. Decrease of dilution and increase of extraction without increased mining costs can be reached through replacing the mining system by that without a compensatory area. However, this requires considerable expenses on workings and their maintenance.

Thus, it is necessary to enhance the technology of underground mining of blocks under rock pressure

around them to ensure efficient extraction and decreased mining costs.

3 Results and discussion

The technique of determining the line of the least resistance and distances between borehole ends should be applied when determining parameters of blasting and drilling operations [25, 36, 37, 40].

Such techniques differ in breaking conditions and estimation criteria. Thus, when mining iron ore deposits, there are applied methods based on placing explosives in the massif depending on stress concentration, rock hardness, qualitative characteristics of explosives, etc [15, 16, 37].

Analysis of methods of determining parameters of drilling and blasting enables building dependencies of changes in the line of the least resistance on the borehole diameter when using *Grammonite 79/21*, Fig. 1.

Fig. 1. Dependencies of changes of the line of the least resistance on a borehole diameter when applying various calculating methods.

The graphs in Fig. 1 demonstrate that the analyzed methods for determining the line of the least resistance do not differ significantly from each other and the error does not exceed 20%. Therefore, the new technique developed by Yu. P. Kaplenko is used for further investigations and calculations. The technique is widely applied at the underground mines of Kryvyi Rih iron ore basin [37].

The line of the least resistance (LLR), the distance between borehole ends and specific consumption of explosives for breaking in terms of ore hardness are determined by the formulas [37]:

$$W = k_n \times C_o \times d_{pr}, \text{ m}; \quad (1)$$

$$a = m \times W, \text{ m}; \quad (2)$$

$$q = \frac{2 \times k_z \times U}{a \times W \times \gamma}, \text{ kg/t}. \quad (3)$$

The results of the calculations enable building a dependency of LLR (Fig. 2), the distance between borehole ends (Fig. 3) and specific consumption of explosives for breaking (Fig. 4) on the diameter of the borehole and the ore hardness factor.

Fig. 2. Dependencies of LLR on the borehole diameter and the hardness factor.

Fig. 3. Dependencies of the distance between borehole ends on the borehole diameter and the ore hardness factor.

The graphs in Fig. 2 demonstrate that with rock hardness of 13 and the borehole diameter from 89 mm to 250 mm, LLR increases from 2.1 to 6 m and specific consumption of explosives grows from 0.8 to 0.9 kg/t (see Fig. 4).

The graphs in Fig. 3 demonstrate that with the increase of the borehole diameter from 89 to 250 mm the distance between borehole ends grows from 1.8 to 5.3 at the ore hardness factor of 12.

Thus, when ore hardness increases, the line of the least resistance, the distance between borehole ends and

specific consumption of explosives for breaking grow. This corresponds to the practice of using *Grammonite 79/21* when mining iron ores at Kryvyi Rih basin.

Fig. 4. Dependencies of specific consumption of explosives for breaking on the borehole diameter and the ore hardness factor.

According to research data [36], displacement of the compressing material in the stope makes 2–2.5 m after explosion of the first row of boreholes and reaches 3 m after explosion of 4–5 rows of boreholes (or 3 rows of parallel contiguous boreholes) and then it stops. Compaction occurs in the stope area with the width of 25–30 m (or 60–80 m at the average ore hardness and rather thick ore bodies). According to the investigation results, movement of the previously broken ore or caved rock of the adjacent panel on which the ore is broken makes 1–1.2 m [36].

Displacement of the compressed material depends, first of all, on thickness of the ore layer to be caved. Displacement and compaction occur unevenly depending on the distance from the compressing material; so the farther the distance from the contact separating caved rocks and ore massif is, the smaller displacement and compaction are.

Change of the compressing rock layer from 25 to 15 m does not produce any noticeable impact on the fragmentation factor of ore and rock on the contact. Major displacement occurs not far (2 – 15 m) from the contact surface. Besides, after the first explosion, compaction and movement of the material occur not far from the contact surface. After subsequent explosions, displacement of the compressing material decreases as forces of internal friction and adhesion that appear in the compacted compressing material obstruct displacement of caved ores and rocks [36, 40].

Displacement of the compressed material in the compressed environment depends on the fragmentation factor of ore mass and thickness of the caved compressing material. The volume of the compressing material after movement is calculated by the expression [36]

$$V_1 = (L - \Delta t) \times h \times M, \text{ m}^3, \quad (4)$$

where h , L , M are height, width, thickness of the mining block, m; Δt is thickness of the layer when breaking in the compressed environment, m.

Transformations of expression (4) considering volumes of the layers that are broken and over-compacted with the corresponding primary fragmentation factor result in the following expression for determining thickness of the layer when breaking in the compressed environment

$$\Delta t = \frac{L \times (K_r - K_{r1})}{K_r}, \text{ m}, \quad (5)$$

where K_r , K_{r1} are the fragmentation factors in the block and the compacted layer respectively

Possible displacement of the compressed layer considering the factor of ore fragmentation in the compressed layer is determined by the formula

$$l = \frac{\Delta t}{(K_{u,r} - 1)}, \text{ m}, \quad (6)$$

where $K_{u,r}$ is the average factor of ore fragmentation after blasting.

It should be noted that in laboratory conditions this formula is only true if width of the broken layer does not exceed 15 m. Calculations by formula (6) enable building dependencies of changes in thickness of the layer onto which ore is compressed on that of the broken ore massif layer, Fig. 5.

Fig. 5. Dependency of thickness of the ore layer onto which broken ore is compressed on that of the broken ore at the fragmentation factor of caved ore in the over-compacted layer of: 1, 2, 3, 4 – 1.4, 1.3, 1.2 and 1.1 respectively.

The graphs in Fig. 5 demonstrate that increase of the layer of the ore massif to be broken causes increase of the compressing layer width at the sufficient supply of the massif with explosives (i.e. simultaneous firing of 3 rows of parallel contiguous borehole rounds).

Thus, increase of the width of the layer of ore to be broken from 2 to 10 m causes increase of thickness of the compressing layer from 0.3 to 2.7 m at the decreased

primary fragmentation factor in the over-compacted layer from 1.4 to 1.1.

The compaction factor mainly depends on the amount of explosives for ore breaking and compaction.

Transformations of equation (5) and its solution with respect to t_{st} result in the general formula for determining thickness of the ore layer to be broken on caved rocks in the upper part of the block

$$t_{st} = \frac{h \times (K_r - K_{r1})}{K_r \times (K_r - 1)}. \quad (7)$$

Analysis of the expression enables concluding that in practice thickness of the compressed material layer should be determined applying the grapho-analytical method.

Dependencies of thickness of the broken layer on height of the caved layer and the primary fragmentation factor in the over-compacted layer at the primary fragmentation factor of 1.5 are given in Fig. 6.

Fig. 6. Dependencies of thickness of the broken layer on height of the caved layer and the primary fragmentation factor in the over-compacted layer at the primary fragmentation factor of the caved layer of 1.5: 1, 2, 3, 4 – the primary fragmentation factor in the over-compacted layer is 1.1, 1.2, 1.3 and 1.4 respectively.

Fig. 6 demonstrates that increase of the broken ore thickness (stope height) causes possible increase of thickness of the layer to be caved. Thus, at the necessary factor of primary fragmentation of the over-compacted layer of 1.2, increase of the caved layer height from 15 to 45 m results in growth of thickness of the caved crown from 6 to 17 m.

When drawing under caved rocks from panels with inclined walls, part of the ore does not enter the area with drawpoints as ore drawing under the caved rocks is conducted at the angle of 60–85°.

It should be noted that expression (7) is true when the block is not impacted by external forces. At underground

mining of deposits, rock pressure caused by caved rocks located over the caved ore layer changes depending on the depth of mining, Fig. 7.

Fig. 7. The chart for determining displacement (movement) of the material to be compressed depending on the caved ore layer considering impacts of external forces.

On this basis, thickness of the layer of ore broken onto caved rocks considering pressure around the mining block is determined by the formula

$$t_{st} = \frac{h \times (K_r - K_{r1})}{K_r \times (K_r - 1)} \times K_\sigma, \text{ m}, \quad (8)$$

where K_σ is the factor considering rock pressure around the mining block.

The pressure coefficient is determined by relation of rock pressure around the block before and after crown caving and calculated by the formula

$$K_\sigma = \frac{P_1'}{P_1}, \text{ m}, \quad (9)$$

where P_1 is pressure on the crown before its caving, MPa; P_1' is pressure on the block after crown caving, MPa.

It should be noted that formula (9) is true when the marginal condition is fulfilled

$$P_1 \geq P_2 \leq P_1'. \quad (10)$$

Analysis of formula (8) enables concluding that:

- when pressure in the upper part of the mining block decreases, after caving the crown, movement of rock mass is observed in both directions (according to the research into breaking ore in the compressed environment) [21, 26, 40]. That is, not only caved ore but also caved rocks will be compacted;
- when pressure in the upper part of the mining block increases, after caving the crown, rock mass will move towards areas with lower rock pressure [36-40].

Harmful influence caused by borehole shooting in the ring can be decreased through out-of-turn borehole firing

in the ring.

Quality of ore breaking depends on even distribution of explosives on the whole area of ore to be broken.

The conducted investigation enables suggesting bulk caving of ore and overlying rocks with breaking ore on the compressed environment by deep boreholes of 250 mm in diameter (Fig. 8).

This option of mining systems implies the following. The deposit is divided into 50–60 m long blocks along the strike. Vertically, a level is divided into 2-3 sublevels depending on the dip angle of the ore body.

Preparation of a block starts from driving access crosscuts from the haulage entry and drilling ventilation and manway raises on the block sides, Fig. 8. Then, ventilation and manway crosscuts are driven from the ventilation and manway raises. Service and ore discharge raises are driven to the crosscuts from the haulage level.

Two scraper entries are driven from the ventilation and manway crosscuts at the distance of 10 m from each other. The scraper entries are connected by the ventilation crosscut. 7 m high drawpoints go out of the scraper entry to the undercut level. Then, at the distance of 10 m from the scraper level, a drill drift is driven in the footwall. After that, stoping is performed.

Above the scraper level, a slot is formed through driving a 3 m wide cut raise and then 105 mm diameter boreholes expand it to the thickness of the ore body. Then, blast holes are drilled for draw points. After that, blast holes and boreholes are fired and part of the broken ore is drawn from the block.

Next, a sublevel is drilled by rings of deep boreholes from the drill drift. Breaking of the panel reserves starts immediately after creating the slot.

The drilling rig NKR-100M is used to drill 2 rings of deep boreholes of 250 mm in diameter from the drill drift. Then, the boreholes are charged and fired.

The block massif is drilled by drilling rigs with a reamer. First, a pilot hole of 155 mm in diameter is drilled, and then the hole is reamed to 250 mm. The P150S downhole hammer and the KNSH-155 bit are used for drilling. The reamer K-250 is used to ream the borehole to 250 mm [36,40].

In conformity with the determined parameters of the slot and the ore layer of the massif to be broken, the primary fragmentation factor is 1.35. To blast the massif, millisecond-delay and delay-action electric detonators are used. After caving the first ore layer and creating the over-compacted layer, 20% of ore is drawn. Next, 4-8 rings of deep boreholes are drilled and blasted.

After caving the main part of the reserves, the crown is caved through drilling rings of deep boreholes onto the caved ore compacting the upper and lower layers, Fig. 8.

After the block is broken, ore is drawn and hauled at the receiving level by the scraper winch 30LS-2S into ore passes and then vibrating feeders ASHL-2 load it into cars VG-10A.

It should be noted that when breaking onto the compressed environment by 105 mm boreholes, breaking by parallel contiguous boreholes is applied, i.e. 2 rings are drilled in parallel. In case 250 mm boreholes are applied, distance between their ends is decreased, Fig. 8.

Fig. 8. Drilling by vertical rings of deep boreholes of 250 mm in diameter onto the compressed environment.

The results of the calculations of blasting and drilling by deep boreholes of 105, 250 mm in diameter with breaking ore onto the compressed environment are given in Table 1.

Table 1. Basic technical and economic indicators when grilling deep boreholes.

Name	Borehole diameter:	
	105 mm	250 mm
Balance reserve of ore in a block, t	189000	189000
Line of least resistance, m	2.8	6.6
Distance between borehole ends, m	2.6	6.1
Total length of boreholes, m	23904	4310.4
Total explosives, kg	153737.5	124804.4
Ore yield per 1 m of borehole, t	7.9	43.8
Specific consumption of explosives, kg/t	0.81	0.66
Average piece diameter, m	0.21	0.37
Oversize, %	34.3	1.1
Labour efficiency at breaking, t/shift	314.4	581.8
Specific labour expenses (drillers), USD	1.36	0.74
Specific labour expenses (chargers and shotmen), USD	0.94	0.76
Other materials and equipment, USD	0.34	1.18
Drilling and blasting costs, USD/t	12.40	10.6

Advantages:

1. Boreholes of 250 mm in diameter increase efficiency, depth and accuracy of drilling. One 250 mm borehole corresponds to 6 – 7 bundled boreholes of 105 mm in diameter.
2. Suitable for use in weak and instable packing-average ores.
3. No caving of hanging wall rocks

Disadvantages include the following: after drawing first portions of ore, expenses on secondary crushing of ore compacted by blasting increase; application is constrained.

The results of the conducted calculations prove that specific consumption of explosives does not differ significantly. In addition, it should be noted that the increased diameter of boreholes leads to reduction of their length from 23.9 thousand m (105 mm) to 4.3 thousand m (250 mm).

Ore breaking costs decrease from 12.4 or 12.67 to 10.6 USD/t. Thus, benefits from using boreholes of 250 mm in diameter for breaking are expected to make 1.8 USD/t. In terms of a mining block, the economic effect will make 340.2 thousand USD. With the annual output of 2.4 mln t, the annual economic effect will make 4.32 mln USD.

The work was supported by the Ministry of Education and Science of Ukraine within the framework of the state scientific topics “Determination of regularities of the stress-strain state of rocks disturbed by workings with the purpose of developing resource-saving ore mining technologies” (State registration No. 0115U003179).

Research of new methods for quality air control after massive explosions in the open mine industry

Natalya Shvaher*, and Tatyana Komisarenko

Kryvyi Rih National University, Department of labor protection and civil security, 11 Vitalii Matusevych Str., Kryvyi Rih, 50027, Ukraine

Abstract. The aim of this study is to analyze the existing methods to determine the presence of harmful substances in the open pit atmosphere after massive explosions, and to develop a method of measuring the gas composition of the atmosphere using unmanned aerial vehicle (UAV). Existing methods of controlling the whole open pit atmosphere and its individual sections do not meet safety requirements. The main disadvantages are that workers should be present at danger zone and they are exposed at risk of poisoning by harmful gases. In addition, these methods require considerable time for delivery and analysis of samples in the laboratory, and the results contain significant measurement errors. Therefore, it is necessary to develop a methodology to determine the presence of harmful substances in the open pit atmosphere after massive explosions using UAV device, and conduct analytical research of signal dissemination to UAV control in the air. It was established that the implementation of the proposed method will allow to get quickly reliable data on the chemical composition of atmosphere in the explosion areas. It is possible to carry out the control measurements during mining operations without their interruption and without people presence in the dangerous area which allows to increase safety.

1 Introduction

Proven reserves of the iron ore for Kryvorizkyi Iron Ore Basin are one of the largest in Europe, about 32.2 billion tons, with an iron content in the ore from 22-65% [1-4]. Mining works are carried out using open and underground methods. It should be noted that minerals containing iron from 22 to 36% are exploited by open pit mining and minerals containing iron from 48 to 65% by underground mining [5-8]. Underground methods are traditionally designed using chamber system or using massive ore body collapse methods by deep wells, which reduces iron ore containing from 65% to 58-62%. It should be noted that the production cost of underground mining is much higher than open pit methods (by 2-3 times) [9-11].

To reduce production costs in underground mining works the system design is continuously improved by increasing the iron content in the mined ore mass (60-62.5) which allows to reduce the difference in the cost of production by 1.8-2.7 times [12-14].

Significant reduction in the cost of iron ore underground mining is possible by use of imported equipment and use of emulsion explosives "Ukrainit" [15-16]. To improve conditions of mining ore extraction, it is proposed to increase the diameter of the holes up to 250 mm, which significantly reduces the extraction cost. However, this enhancement will significantly worsen the

mine air, and with the present mechanization level, it will increase the cost of ventilation.

Thus, the open pit mining is currently providing a significant level of mechanization, productivity and economic performance, but has a negative impact on the environment, namely on the air quality.

Massive explosions in quarries are accompanied by the formation of powder-gas cloud of dust 0.030-0.19 kg/m³, carbon monoxide - 60-95 l/kg and nitrogen oxides – 3.5-7 l/kg. Hazardous substances formed during an explosion reach high overtime concentrations in the open pit mine air. Therefore there is a negative impact on the workers and residents of adjacent areas health [17]. It should also be noted that even after required time of ventilation in the working area, blasted rock still releases toxic gases. After mass explosion, content of carbon monoxide into the blasted rock is 4-5%, and nitrogen oxides up to 0.06%. A significant danger to workers represent remaining after the explosion dust and gas, which exude from the blasted rocks and pollute the air of the blasted blocks.

Today the most common way in Kryvbas quarries to determine the presence of hazardous substances (carbon monoxide CO, carbon dioxide CO₂, methane CH₄, nitrogen oxide NO, nitrogen dioxide NO₂) and of the dust after an explosion is a measurement carried out by a group of specialized employees directly on-site. Atmosphere measurements are conducted by pumping the air through the samplers in different parts of the blasted blocks. Then air samples are delivered to a

* Corresponding author: knu.shwager@gmail.com

laboratory, which decides on the admission of workers in the explosion area [18-21].

The main drawback of this method is the presence of workers in the danger zone and therefore a risk of poisoning by harmful gases and dust. In addition, this method requires considerable time for delivery and analysis of samples in the laboratory. The results of measurements by this method unreliable because the sampling is conducted at the ground level of blasted rocks.

The method makes impossible determining of the atmosphere changes at several meters height and also during mining works, where gas emissions continue from the blasted rocks. [22-23]

Another way to control harmful substances is a method developed by Research Institute for Safety and Ecology in the Mining and Metallurgy Industries [24], it consists in the installation on a distance of 20-30 m from the blasted blocks border of hydro-mechanical and electromechanical devices for air sampling. After the explosion, under the influence of seismic waves occurs triggering of these devices. When block access is allowed, an analysis of gas concentration is conducted. Sampling takes place in special containers.

A well-known is a way of determining the presence of harmful substances, using a discrete measuring of the atmosphere chemical composition on the set trajectory around the geometric center of the blasted rocks. In the blasted blocks is installed on the ground a set of individual devices to sampling the air quality, consisting on placing them in concentric ellipsoid conventional lines (trajectories) around the geometric center of the blasted rocks. Ellipsoid lines form should take into account the direction and speed of wind [25]. Each atmosphere sampling block consists of a number of devices for sampling, which is equal to the number of sampling points accordingly to the regulations for the air quality control. Once installed, the sampling units are powered and remote controlled from a safe place. After the explosion and appearance of the gases, the device is periodically activated remotely according to adopted regulations for air quality control in the atmosphere. After the sampling, the samples from these devices are delivered to a laboratory in order to analyze the chemical composition of the atmosphere air.

The disadvantage of this method is its low reliability because there are a number of sampling units that are placed in the explosion area on the ellipsoid trajectory, therefore the devices may be damaged by pieces of blasted rock. In addition, this method is highly labor intensive and requires highly skilled and specially trained workers. During samples recovery from the devices, the workers are exposed at risk of poisoning by harmful gases and by dust. The method doesn't allow to quickly determine the changes of air chemical composition, because of the blasted rock emissions of harmful gases and dust, after the loading operations. Moreover, in case of wind direction change, the results will be distorted.

Another way to control the quality of atmosphere air, which is similar in terms of technical realization and obtained results to the one described above, is to control

the atmosphere gas composition after an explosion, using unmanned aerial vehicle (UAV), which carries out a discrete measuring of the chemical composition of air in the trajectory around the geometric center from the blasted rock at some given points. UAVs are equipped with portable gas analyzer with gas and dust detectors, onboard computer, electronic altimeter and navigation. The trajectory of UAV has the form of horizontal rectangles, geometric center of which coincides with the geometric center of the blasted rocks area. A portable gas analyzer automatically saves the measurement at a preset time and transmits the obtained results to on-board computer. A signal from UAV is transmitted to the ground station computer. Using navigator, it is possible to track and record the trajectory of UAV at the fixed height from the ground which is set and controlled by an electronic altimeter [26, 27].

One of the most important characteristics is the autonomy of action and maximum range of a UAV. Compared to the other methods of control, such as direct sampling or aircraft use, the UAVs autonomy is crucial.

2 Methods

The area of mass explosions in opencast mines of Kryvbas depends on the deposit geological characteristics, for example, the width of blasted rocks area may start from 20 meters and the length starts from 200 m [26].

In this study, we consider several options for mass explosion area in order to compare the data and to identify the necessary autonomy. In addition, it is necessary to add the distance from the safe place to the work area. This distance taken from 500 m to 1000 m (in the worst case).

UAV must conduct exploration and analysis of the air after a massive explosion, its schematic trajectory of flight is shown on the Fig. 1.

Fig. 1. Schematic trajectory of UAV movement to measure air quality after massive explosion.

For parameters of the block, we consider the block length $A = 300$ m and block width $B = 30$ m, the total length of trajectory flown over by UAV (P) is calculated

below using a pitch $l = 5\text{m}$.

$$P_{\text{measures}} = (A / l \cdot L) + (A / l \cdot l), \text{ m} \quad (1)$$

$$= P(300/5 \cdot 30) + (300/5 \cdot 5) = 2100 \text{ m} \quad (2)$$

It is also necessary to take into account the distance from the shelter to the mass explosion area, in this case $P_{\text{shelter}} = 2 \times 1000 \text{ m} = 2000 \text{ m}$. Generally, UAVs must travel a distance of at least 3 km in order to carry out measurements in the mass explosion area.

The velocity of the UAV will be different at each stage of trajectory, UAV velocity during the flight from shelter to work area V_{shelter} will be different from the velocity during the measurements V_{measures} . The distance from the shelter to the work area the UAV can flight at a speed $V_{\text{shelter}} = 8 - 10 \text{ m/s}$, while for the measurement, UAV is limited to a maximum speed V_{measures} at 2 – 3 m/s to ensure the measuring performance.

Thus, we get:

$$T_{\text{total}} = P_{\text{shelter}} / V_{\text{shelter}} = 2,100 / 8 = 263 \text{ s}, \quad (3)$$

taking 5 minutes.

$$T_{\text{measures}} = P_{\text{measures}} / V_{\text{measures}} = 1000 / 2 = 500 \text{ s}, \quad (4)$$

taking approximately 9 minutes

Thus, autonomy of UAVs must be at least 14 minutes, under ideal operating conditions (with no wind). Therefore, to choose UAVs, it is necessary to consider models with an autonomy more than 30 minutes, and with a cruising speed of 8 – 10 m/s in order to ensure reliable operations without any risk to lose the equipment. It is also necessary to consider a model with autonomous action radius of 2 – 3 km.

The career's air after a mass explosion is quite heterogeneous. Let's consider a spreading beam with a wavelength $\lambda = 12 \text{ cm}$. We also consider the forces acting on dust particle as shown on the figure below (Fig. 2):

Fig. 2. The forces acting on dust particles in the air.

Power Archimedes: $F_A = M_a \cdot g$, where M_a particle mass of displaced air. The air's density is $\rho_0 \text{ (kg/m}^3\text{)}$ and to simplify we use a spherical particle with radius r . In this case:

$$F_A = \frac{4}{3} \cdot \pi \cdot r^3 \rho_0 \cdot g \quad (5)$$

R – is the resistance of air (N). According to Stokes' law:

$$R = 6 \cdot \pi \cdot \mu \cdot r \cdot U \quad (6)$$

where μ – is air's viscosity, $P_a \cdot \text{s}$; U – is particle's velocity (m/s).

In the case of linear movement during the particle's fall if the forces are equal, we can find the velocity of dust particles fall:

$$U = \frac{2}{9} \cdot \frac{\rho - \rho_0}{\mu} \cdot r^2 \cdot g \quad (7)$$

From this expression, it follows that after the explosion, the particles with a large radius and high density fall fast. So after some time, it will remain in space the dust particles with a size which will satisfy the condition $r < \lambda$ (12 cm).

In this regard, these particles can be called “the smallest” (Fig. 3). To these particles we can apply the Rayleigh-Mie theory.

Fig. 3. The interaction of electromagnetic waves with the “smallest particle”.

In this case, the functions included in the number of scattering coefficients a_N and b_N , can be expanded in power series and keep only a few firsts members:

$$\begin{cases} \psi_1(Z) = \frac{Z^2}{3} - \frac{Z^4}{30}; \psi'_1(Z) = \frac{2 \cdot Z}{3} - \frac{2 \cdot Z^3}{15}; \\ \xi_1(Z) = -\frac{i}{Z} - \frac{iZ}{2} + \frac{Z^2}{3}; \xi'_1(Z) = \frac{i}{Z^2} - \frac{i}{2} + \frac{2 \cdot Z}{3}; \\ \psi_2(Z) = \frac{Z^3}{15}; \psi'_2(Z) = \frac{Z^2}{5}; \\ \xi_2(Z) = -\frac{i^3}{Z^2}; \xi'_2(Z) = \frac{i}{Z^3}. \end{cases} \quad (8)$$

Using this approach, the first four amplitude coefficients are equal:

$$\begin{cases} a_1 = -\frac{i \cdot 2\alpha^3}{3} \cdot \frac{m'^2 - 1}{m'^2 + 2} - \frac{i \cdot 2\alpha^3}{5} \cdot \frac{(m'^2 - 2)(m'^2 - 1)}{(m'^2 + 2)^2} + \\ \quad + \frac{4a^6}{9} \left(\frac{m'^2 - 1}{m'^2 + 2} \right)^2; \\ b_1 = -\frac{i\alpha^5}{45} (m'^2 - 1); \\ a_2 = -\frac{i\alpha^5}{15} \cdot \frac{m'^2 - 1}{2m'^2 + 3}; \\ b_2 = 0. \end{cases} \quad (9)$$

Expansion for the amplitude scattering coefficients of higher order containing the members of order α_7 and above. If $|m'| \cdot \alpha < 1$, therefore $|b_1| < |a_1|$

Taking this assumption, we can leave only the first partial electric wave.

$$a_1 = -i \cdot \frac{2 \cdot \alpha^3}{3} \cdot \frac{m'^2 - 1}{m'^2 + 2}. \quad (10)$$

In this case, the weakening efficiency factor will be determined by the expression:

$$Q_0 = 4\alpha \operatorname{Im} \left\{ \frac{m'^2 - 1}{m'^2 + 2} \cdot \left[1 + \frac{\alpha^2}{15} \left(\frac{m'^2 - 1}{m'^2 + 2} \right) \cdot \frac{m'^4 + 27m'^2 + 38}{2m'^2 + 3} \right] \right\} + \frac{8}{3} \alpha \operatorname{Re}^4 \left(\left| \frac{m'^2 - 1}{m'^2 + 2} \right|^2 \right). \quad (11)$$

To determine the scattering efficiency factor, we use the following formula:

$$Q_p = \frac{8}{3} \cdot \alpha^4 \left| \frac{m'^2 - 1}{m'^2 + 2} \right|^2. \quad (12)$$

If

$$|m'| \cdot x < 1, \quad (13)$$

$$Q_0 = 4\alpha \cdot \operatorname{Im} \left(-\frac{m'^2 - 1}{m'^2 + 2} \right) = 4 \frac{2\pi r m_0}{\lambda_0} \cdot \operatorname{Im} \left(-\frac{m'^2 - 1}{m'^2 + 2} \right), \quad (14)$$

$$Q_p = \frac{8}{3} \cdot \frac{(2 \cdot \pi \cdot r \cdot m_0)^4}{\lambda^4} \left| \frac{m'^2 - 1}{m'^2 + 2} \right|^2. \quad (15)$$

To determine the scattering coefficients K_0 and K_p in this approach we use the following expression:

$$K_0 = \frac{6 \cdot \pi \cdot m_0}{\lambda_0} \operatorname{Im} \left(-\frac{m'^2 - 1}{m'^2 + 2} \right), \quad (16)$$

$$K_p = \frac{4 \cdot \pi \cdot m_0}{\lambda_0} \cdot \alpha^3 \cdot \left| \frac{m'^2 - 1}{m'^2 + 2} \right|^2. \quad (17)$$

In the transition to the dielectric constant $m = n - ix$;

$$m^2 = (n^2 - x^2) - i2 \cdot \pi \cdot x = \varepsilon_1 - i\varepsilon_2, \quad (18)$$

We obtain from the following formula:

$$K_0 = \frac{6 \cdot \pi \cdot m_0}{\lambda_0} \operatorname{Im} \left(-\frac{\varepsilon_1 - m_0^2 - i2 \cdot n \cdot x}{\varepsilon_1 + 2 \cdot m_0^2 - i2 \cdot n \cdot x} \right) \quad (19)$$

$$K_p = \frac{4 \cdot \pi \cdot m_0}{\lambda_0} \cdot \frac{(2 \cdot \pi \cdot r \cdot m_0)^3}{\lambda_0^3} \left| \frac{\varepsilon_1 - m_0^2 - i2 \cdot n \cdot x}{\varepsilon_1 + 2 \cdot m_0^2 - i2 \cdot n \cdot x} \right|^2. \quad (20)$$

Thus, the problem of the remote beam spread is resolved. With a weak dependence of the complex refractive index material particles m on the wavelength λ the attenuation coefficient is: $K_0 \approx 1 / \lambda_0$, and $K_p \approx 1 / \lambda_0^4$.

The main task of the UAV is to obtain a reliable data on the atmosphere chemical composition at sites located in the area of the mass explosion. This data should include the air composition at different altitudes without people's presence and also to provide rapid control of the atmosphere chemical composition during rock loading operations [28-30].

The technical result of this proposed model allows to dramatically reduce the atmosphere control time, to obtain a reliable data after the mass explosion, and during the loading operations and exclude the participation of specially trained workers in dangerous area. Therefore, this method allows to increase a safety of workers.

According to the proposed method, measuring of the atmosphere gas composition is conducted using an unmanned UAV unit (Fig. 4), which is equipped with independent engines 1, portable gas analyzer 2, dust detectors 3, on-board computer 4, equipment to store the measurement data 5, electronic altimeter 6 and navigator 7.

Fig. 4. Schematic diagram of the UAV (unmanned aerial vehicle).

The on-board computer generates a radio signal and transmits it to the ground computer. Movement trajectories of UAV (Fig. 5) have the form of horizontal rectangles 9, with a set of atmosphere measurement points 10. The length and width of trajectories 9 cover the entire surface of blasted rock and the geometric center 11 of the trajectories 9 which coincides with the geometric center 12 of the blasted rock.

The parameters of smaller concentric rectangular trajectories 13 are determined based on the adopted regulations to control the atmosphere. The UAV movement trajectories 9 include the different heights H_1 , H_2 , H_3 from the surface.

To ensure reliable measurements of particles, the UAV is equipped with additional camera by which is conducted aerial photographing during the gas composition measuring.

The calculation of the harmful substances concentration at massive explosion is carried out by the authors [31, 32], it allows to conclude that the concentration of carbon monoxide, nitrogen oxides and dust in the atmosphere exceeds the maximum permitted level. This creates a critical situation because of air pollution in the working area.

The intensity of air pollution depends on the properties and state of the rock, weather conditions, equipment and technology, efficacy of methods of dust and harmful gases control.

In this regard, the level of dust and of air pollution in the workplace may vary widely. Significant impact on career's air quality has the composition and moving direction of air flows, which in many cases determines the amount of contaminants. To solve this problem, it has been proposed a method to control by the UAV the gas composition in carrier's atmosphere after mass explosion.

Fig. 5. UAV movement trajectory [26].

3 Results and discussion

Implementation of the proposed method to control the career's atmosphere after the mass explosion will allow to quickly obtain a reliable data on the air chemical composition in mass explosion areas without people's presence, and without interruption of mining operations.

This method to control the career's atmosphere and the gas composition after mass explosion, including discrete measurements of chemical composition on the trajectory around the geometric center of the blasted rock at given points, consists by measurement of gas composition using UAV, whose is equipped by a portable gas analyzer with gases and dust detectors, an on-board computer, an electronic altimeter and a navigation. UAV trajectory has the form of horizontal rectangles, which geometry center coincides with the geometric center of the blasted rock area. UAV use a portable gas analyzer which automatically saves the current measurement at preset time, with the transmission of the obtained results from on-board computer.

Measurements of the atmosphere chemical composition are done at the different heights from the surface. UAV is equipped with additional cameras by which is conducted an aerial photographing during the measuring of the atmosphere gas composition; the measurements data is compared to the coordinates at given points during UAV's flight path.

Thus, the use of UAV for determining the concentration of harmful gases after massive explosions allows to avoid the human presence in the dangerous area and to obtain quickly the information

about air quality (the total time to collect and process the information would not exceed 1 hour). The disadvantages of the method is the relatively high cost of the equipment.

Identification of the process of hydromechanical extraction of amber

Zinovii Malanchuk, Valerii Korniyenko*, Yevhenii Malanchuk, Andriy Khrystyuk, and Mykola Kozyar

National University of Water Management and Environmental Management, 11 Soborna Str., Rivne, 33028, Ukraine

Abstract. The article deals with the method of hydromechanical extraction of amber from sand deposits. The essence of hydromechanical method of amber extraction is considered. The process of extraction has been identified. The analytical expressions obtained for calculating the parameters of hydromechanical extraction of amber from sand deposits, and in particular the expression for determining the rate of emergence of an amber particle, can be used in the further engineering calculations of process parameters and process equipment. These expressions will allow to accurately substitute and with sufficient accuracy to calculate the parameters of the process of extracting amber from amber-containing deposits, as well as to set the parameters of technological equipment for the implementation of this process.

1 Introduction

The essence of the above method is that the array is saturated with water and activated by mechanical excitation to form a continuous slurry of such density at which there is an ejection force that raises the amber on the surface of the deposit. Mechanical action, when present in an array of water, causes the array to completely lose the bond between the particles, release the amber and reach a suspension state with a density greater than the specific gravity of the amber, which allows the latter to float to the surface of the field at the expense of the field.

To implement the method, it is necessary to dip the rods in the amber array in the form of pipes from which water and air are supplied and on which mechanical exciters are fixed. The array is saturated with water and the working body is oscillated. Amber is released from the environment and floats to the surface [1].

The process of soil liquefaction is as follows. In the amber array vibrating method immerses rods with biconical vibrators while simultaneously feeding water and air into the soil array through them. The array of vibrators is oscillated, thus forming a zone of continuous boiling of the soil. Amber separates itself from the massif and under the action of ejection force floats to the surface. The suspension medium allows the vibration device to move freely in the longitudinal direction.

The use of vibrating gear for the extraction of amber from the fields allows achieving the extraction of amber from the field, increasing labor productivity and reducing energy intensity and negative man-made environmental impact on the environment [2].

To increase production volumes while reducing cost, the industry requires the introduction of advanced technologies in amber production. In the absence of

financing in this sector, investments from the state are absent. Amber mining is an outdated method that requires a great deal of money and time to extract and process large amounts of soil to produce amber. Figure 1 shows a diagram of one of the largest amber fields in Ukraine.

Fig. 1. Klesiv amber deposits.

Thus, today, amber production requires new technologies and the development of means to intensify the extraction process, which achieves high productivity and efficiency, and also reduces the negative environmental impact on the environment [3-9].

2 Methods

The northern regions of the Rivne region are characterized mainly by the occurrence of amber in sandy soils, characterized by water and air pores present

* Corresponding author: kvja@i.ua

between the soil skeleton. between them, the Sandy soil moves into a mobile state when the equilibrium between the soil skeleton and the water pores is disturbed, and the slight influence of the hydraulic flows can cause the mass to shift and the considerable mass of the soil to a liquefied state. The transition of water-saturated sands to the liquefied state causes destruction of the structure of the sands and their compaction under the influence of their own weight or external influences. When the sand is thinned, the bearing capacity is lost completely or partially, and the fluid state arises as a result of the destruction of the structure and displacement of the sand particles relative to each other, which is accompanied by the formation of a denser particle arrangement and a decrease in porosity.

The liquefaction phenomenon occurs when the structure and possibility of sand compaction are destroyed; full or close to full saturation of sand with water.

In the course of research, the amber sand deposit at the initial stage enters the state of vacuum, and in the subsequent there is its compaction. The duration of water saturated sands in the rarefied state is much shorter than the time of soil compaction. In our opinion, and based on the results of the analysis of literature sources, the compaction process is more investigated than the liquefaction process, so experimental studies of the liquefaction process, the flow of the process of reaching the surface of amber and the time of transition of sandy soil to the compacted state require additional research. In order to create the necessary conditions to reach the surface of the amber, it is necessary to investigate the parameters of vibrational impact and the use of water and air when exposed to a sandy field.

In conducting experimental studies, we studied the environment of amber, while simulating the boiling process and conducted research on the factors and parameters that affect the creation of the suspension environment.

Studies have shown that the liquefaction structure destroys the sandy amber medium. The sand particles, within the vibration range, are separated from the total array and are brought into oscillatory motion near their equilibrium position and are also moved along some trajectory relative to the vibration source. At the same time there is an intensive movement of gas and water, which take with them sand particles and amber and throw them on the surface. Since the surface of the amber significantly exceeds the area of the particles, under the action of Archimedes force pieces of amber are pushed to the surface.

The following stages of transformation are observed during the vibrational action on a sandy soil mass [2]:

- vibration dilution (maximum preparation for intensive mixing);
- vibration boiling (separation of particles and mixing in the array);
- gradual compaction of the sandy soil mass from the periphery to the vibration source.

The effect of the thinning of the layer is similar to the phenomenon of vibration linearization of dry friction, that is, in the presence of vibration to transfer a particle

of relative motion in the environment requires less constant force than in its absence. As the effective coefficient of friction decreases in the vibration state, the particles slip away relative to one another. The spreading layer is compacted.

From studies [4-8] it is known that the movement of sand in a vibrating fluid bed is not subject to the law of motion of particles in airless space. In addition to gravity, the trajectory of movement of the sand layer is significantly influenced by the parameters of the environment. Throwing produces a rarefaction, while falling - increasing the pressure of the environment. The lower layers of sandy soil have a greater pressure drop than the upper ones, so the air is displaced from below and seals between the particles.

In this way, the vibrating fluidized bed of sandy soil behaves like a pump that pumps a gas-liquid mixture to the surface, taking particles of amber and transporting them to the top. In this case, the rate of rise of the particle from bottom to top depends on the vibrational excitation of the array, the dilution of the medium, saturation with air bubbles and the viscosity of the medium.

The pressure drop depends on the frequency and amplitude of the oscillator, the height of the layer, the particle size and humidity of the sandy soil, as well as the coefficient of friction of the particles one by one. The intensity of the pumping action of the vibrating boiling layer is characterized by three parameters: pressure above and rarefaction under the vibrating boiling layer, pressure drop in the layer.

The following parameters influence the creation of a vibrating fluid layer of soil: 1) oscillation amplitude; 2) oscillation frequency; 3) compelling force; 4) water pressure; 5) air pressure; 6) geometric arrangement of the oscillators.

To a large extent, these parameters are experimentally determined.

Submission into the sand mass of air together with water can intensify the process of lifting the amber to maximum values, but when the air trunks are formed, the boiling process goes into vibration and stops. The maximum rate of flow of amber to the day surface is observed when changing the flow of gas-liquid mixture in the sand array in the range 0 to 0,02 m³/h.

Creating the desired density of the medium depends on the flow of gas-liquid mixture into the array.

Figure 2 shows the results of experimental studies of the simultaneous influence of the oscillation frequency of the working body and the magnitude of the air flow into the sand array, which demonstrate the explicit manifestation of two peak areas of maximum amber flow velocities [10].

On the basis of the obtained experimental dependence, we have the following ranges of values of the oscillation frequency of the working body and the magnitude of the air flow into the amber-containing array: the oscillation frequency of the working body 28-34 Hz; the magnitude of the air flow into the array 0,003-0,006 m³/h, with the speed of lifting amber is the highest and is 0,09-0,12 m/s [10].

Fig. 2. Dependence of the amber rise rate on the frequency of oscillation and the supply of air to the water-saturated array.

3 Results and discussion

3.1 Analysis of models of motion of an amber particle under hydromechanical action

The movement of amber in a sandy massif is characterized by movement with resistance to the type of dry friction. The movement of a particle placed in a medium that performs horizontal oscillations with frequency and radius of the trajectory and produces a particle resistance similar to dry friction. The corresponding problem was considered by V. V. Gortinsky, G. E. Ptushkin and I. I. Blechmann [11]. Here are the main results of the solution and their discussion in terms of hydromechanical amber production. These authors have considered the following system of differential equations of motion of a particle with respect to the medium to determine the rate of emergence of amber

$$m_1 \ddot{x} = m_0 (\Delta - 1) r f^2 \cos ft - F_h \frac{\dot{x}}{\sqrt{\dot{x}^2 + \dot{y}^2 + \dot{z}^2}}, \quad (1)$$

$$m_1 \ddot{y} = m_0 (\Delta - 1) r f^2 \cos ft - F_h \frac{\dot{y}}{\sqrt{\dot{x}^2 + \dot{y}^2 + \dot{z}^2}}, \quad (2)$$

$$m_1 \ddot{z} = m_0 (\Delta - 1) g - F_v \frac{\dot{z}}{\sqrt{\dot{x}^2 + \dot{y}^2 + \dot{z}^2}}, \quad (3)$$

$$\Delta = \rho / \rho_0, \quad (4)$$

$$\sqrt{\dot{x}^2 + \dot{y}^2 + \dot{z}^2} \neq 0. \quad (5)$$

where F_v – the force of resistance to the relative displacement of the particle in the vertical direction, N;
 m_1 – the mass of the particle taking into account the attached mass of the medium, kg;
 m_0 – mass of the medium in volume equal to the volume of the particle, kg;
 $\dot{x}, \dot{y}, \dot{z}$ – projections on the axis of the rectangular coordinate system XYZ of the relative velocity of the particle in the medium, m.

This allowed them to propose the following dependence for determining the rate of emergence of amber [12]:

$$v = \frac{a^2}{\sqrt{\left(\frac{F}{gm}\right)^2 - a^2}} \frac{\alpha}{k_m}, \quad (6)$$

$$\alpha = \begin{cases} Af, & A^2 f < kg \\ \frac{kg}{f}, & A^2 f > kg \end{cases}, \quad (7)$$

$$a = \rho - 1, \quad (8)$$

$$\rho = \frac{\rho_c}{\rho_s}, \quad (9)$$

where v – the rate of emergence of the amber particles, m/s;

m – weight of amber particles, kg;

a – the Archimedes parameter for the amber particle;

g – free fall acceleration, m/s²;

k_m – the coefficient of the coupled mass;

f – frequency of oscillation of the working body, Hz;

F – the force of resistance of the sand layer relative to the motion of the amber particle [12];

ρ_s – density of amber particles, kg/m³;

ρ_c – density of water-sandy environment, kg/m³;

A – oscillation amplitude of the working body, m;

k – coefficient of friction.

Formula (6) is obtained for the case of particle flooding of lower density in the layer of particles of heavier material when the oscillation of the working body in the plane of the surrounding medium [13-17]. In this case, the authors assume that apart from the forces of inertia, Archimedes, and gravity, only the forces of resistance to relative motion are active, and the trajectory of motion of the particle is a spiral.

However, there are no recommendations for determining the magnitude of the force for the conditions under consideration. Given the dimension and nature of this magnitude, as well as the fact that it characterizes the interaction between the amber particle and the soil skeletal particles, the following option is proposed to determine the magnitude of this force

$$\frac{F}{gm} = \phi(1+a), \quad (10)$$

where ϕ – the drag coefficient of the sand medium of the amber particle motion [18].

Substituting the dependence (10) into formula (6), the following expression is obtained for the rate of emergence of an amber particle:

$$\frac{k_m v}{\alpha} = \frac{a^2}{\sqrt{\phi^2 (1+a)^2 - a^2}}. \quad (11)$$

The obtained formula (11) takes into account the influence of the difference in the density of the soil particles and the extracted material, as well as the amplitude and frequency of oscillation of the working body. The effect of the air supply is only taken into account by changing the density of the amber-containing medium.

To determine the magnitude of the coefficient ϕ we will use the results of experimental studies by well-known authors on the emergence of amber particles in laboratory and field conditions [19-29]. In this case, expression (11) will have a more convenient definition for ϕ :

$$\phi = \sqrt{1 + \frac{\alpha}{k_m v} \left(1 - \frac{\rho_s}{\rho_c}\right)}. \quad (12)$$

From the received data it is visible that for the whole interval of the studied values at calculations with engineering accuracy it is possible to use the average value of the coefficient ϕ equal to

$$\phi = 0,325. \quad (13)$$

It follows from formulas (6) - (13) that in hydromechanical extraction of amber from sand deposits, the ratio of the force that impedes the movement of the particle in the bulk medium to the volume of the particle, the density of the medium and the acceleration of free fall is equal to 0,325.

The results of the study of expression (11) on the extreme indicate that this function has a maximum at a point:

$$a_{\max} = \frac{3}{2} \frac{\phi^2}{1 - \phi^2} \left[1 + \sqrt{1 + \frac{8}{9} \frac{1 - \phi^2}{\phi^2}} \right], \quad (14)$$

the coordinate of which at $\phi = 0,325$ is $a_{\max} = 0,6946$.

Thus, it is necessary to consider the motion of the amber particle in the vertical direction, taking into account Archimedes force, vibrations of the working body, as well as the forces of relative resistance of the medium and viscous friction [30-36]. In this case, given the results already obtained and the assumption that the positive direction of the coordinate axis is directed vertically upwards, the equation of motion of the floating particles can be written as follows:

$$(1 + k_m) m \frac{d^2 z}{dt^2} = m_0 g a + m_0 S f^2 \sin ft - F - F_c, \quad (15)$$

$$m = \rho_s \frac{\pi d^3}{6}, \quad (16)$$

$$m_0 = \frac{\rho_c}{\rho_s} m, \quad (17)$$

$$F = \phi m_0 g a, \quad (18)$$

$$F_c = C_x \rho_c \frac{v^2}{2} \frac{\pi d^2}{4}, \quad (19)$$

where z – moving particles of amber, m;

t – time, s;

m_0 – weight of amber-containing sand in the volume of amber particles, kg;

S – the oscillation amplitude of the working body, m;

F_c – the force of viscous friction of an amber particle when moving through a liquefied medium, N;

d – diameter of amber particles, m;

C_x – force coefficient of viscous resistance.

Taking into account recommendations [37-49], we assume that the Stokes regime of the flow of amber particles when moving through a liquefied fluidized medium, for which according to [29] the dependence of the coefficient of viscous drag force on the Reynolds number can be distinguished as follows:

$$C_x = \frac{26}{\text{Re}_c}, \quad (20)$$

$$\text{Re}_c = \frac{v d}{\nu_c}, \quad (21)$$

where Re_c – Reynolds number characterizing the process of interaction of the amber particle with the liquefied medium;

ν_c – kinematic viscosity of the liquefied medium.

Substituting formulas (16) - (21) into equation (15) and having the corresponding transformations, we obtain the following equation of motion of an amber particle through a liquefied medium

$$\frac{d^2 \zeta}{d\tau^2} + f_0^2 \frac{d\zeta}{d\tau} = A_0 \frac{\rho - 1}{\rho} + A \sin a\tau, \quad (22)$$

$$\zeta = \frac{z}{d}, \quad (23)$$

$$\tau = \frac{g d}{\nu_g} t, \quad (24)$$

$$f_0 = \sqrt{\frac{39\sigma}{2(1 + k_m)\rho G m}}, \quad (25)$$

$$A_0 = \frac{(1 - f)}{(1 + k_m)\rho G m}, \quad (26)$$

$$A = \frac{a^2}{(1 + k_m)\rho} \frac{S}{d}, \quad (27)$$

$$a = \frac{\omega \nu_g}{g d}, \quad (28)$$

$$G m = \frac{g d^3}{\nu_g^2}, \quad (29)$$

$$\sigma = \frac{\nu_c}{\nu_g}, \quad (30)$$

$$\rho = \frac{\rho_c}{\rho_s}, \quad (31)$$

where σ – the viscosity ratio of the liquefied medium [10];

ρ – the relative density of the liquefied medium;

ν_g – kinematic coefficient of air viscosity.

The solution of equation (22) is investigated and reported in the specialized literature, and it is proved that the periodic term, when averaging, makes no significant

contribution compared to the stationary component [15]. Thus, the amber medium can be considered as a liquefied layer when the hydromechanical action disrupts the contact between the amber particles and the particles of the array, between the particles of the amber-containing array, but does not directly affect the movement of the amber particles. The effect is to increase the mobility of the particles and the porosity of the array, to reduce the friction between the particles, as well as to obtain an array of viscosities similar to the kinematic viscosity of a liquid substance [29]. That is, the hydromechanical effect creates favorable conditions for the work of Archimedes force, which ensures that the particles of amber float to the surface.

In this case, the equation of motion of the amber particle with hydromechanical action on the amber-containing layer takes the following form

$$v = \frac{2(1-f)}{39} \frac{gd^2}{\sigma v_g} \frac{\rho - 1}{\rho}. \quad (32)$$

Given the ratio of the density of the flooded soil to the air, the relative density of the liquefied medium can be determined by the following formula:

$$\rho = (1 - \varepsilon) \Delta, \quad (33)$$

$$\Delta = \frac{\rho_0}{\rho_s}, \quad (34)$$

where ε – the porosity of the liquefied medium;
 Δ – the ratio of the particle densities of the water-saturated soil to the soil and amber.

The results of experimental studies on the measurement of the density of a layer of water-saturated soil containing particles of amber under hydromechanical exposure with and without air supply show that the porosity of the medium under the considered influence on the soil mass with engineering accuracy can be determined.

At the same time, formulas (32) - (34) should describe the dependence of the flow rate of the amber particles on the air flow, with a characteristic maximum in the neighborhood of $q = 0,015 \text{ m}^3/\text{h}$. Substituting expression (33) into formula (32), it is easy to obtain an expression for the first derivative of q :

$$\frac{dv}{dq} = - \frac{\beta + 2\alpha q}{(1 - \varepsilon)^2} \frac{2(1-f)}{39\Delta\sigma} \varepsilon_\omega \frac{gd^2}{v_g}. \quad (35)$$

It can be seen from formula (35) that the dependence (32) on the variable q is decreasing over the entire interval and has no extremes. This means that in order to adequately describe the processes under consideration, it is necessary to take into account the change in not only the density but also the effective viscosity of the liquefied medium. Similar processes are realized in the processing of bulk material in vibrating, boiling and pulsating fluidized layers [12-24]. The results of the analysis of known mathematical models describing hydrodynamic processes in such layers with steady or pulsed air supply suggest two types of formulas for

calculating the dynamic viscosity coefficient of the liquid medium under consideration [29].

The first group of formulas, to which Einstein's dependencies [15], Vakhrushev, Gupalo, Kunitz, and Todesa [29] include, depend on the degree of porosity without taking into account the influence of other factors:

$$\sigma = \frac{M}{\varepsilon^N}. \quad (36)$$

However, the authors do not indicate what determines the values of the coefficients in formula (36), how to choose them, and how to consider other factors, such as the volume air flow, the size and density of soil particles. The formulas of the second group [15] take these factors more fully into account, which complicates the calculated dependencies and requires their adaptation to the conditions of use.

The maximum effect of these parameters is taken into account in determining the dynamic viscosity of the liquefied medium by the following method [29]:

$$\mu = 0,7282 \frac{g^{1,207} \delta^{2,207} \rho_g^{0,707}}{(v_g - v_0)^{1,414}} \rho_0^{0,293} \sqrt{1 - \varepsilon}, \quad (37)$$

$$v_0 = \frac{v_g}{4,9} \left(\frac{\rho_0}{\rho_g} \right)^{0,1}, \quad (38)$$

where μ – the dynamic viscosity of the liquefied medium;

δ – diameter of particles of soil skeleton containing amber, m;

ρ_g – air density, kg/m³;

ρ_0 – density of water saturated amber medium, kg/m³;

v_g – air speed, m/s;

v_0 – the sliding velocity of particles of amber-containing medium, m/s.

Substituting expression (37) into formula (38), moving from a dynamic coefficient of viscosity to a kinematic coefficient of viscosity, conducting the corresponding transformations and transition to dimensionless quantities, taking into account formula (34), after approximating the dependence of the coefficient of proportionality on the ratio of the density ratio and air by a power function, we obtain the following expression for calculating the magnitude σ :

$$\sigma = k_v \frac{Gm^{1,207}}{\rho \text{Re}_g^{1,414}} \sqrt{1 - \varepsilon}, \quad (39)$$

$$k_v = 0,6898 \Delta^{0,407} \left(\frac{\rho_g}{\rho_s} \right)^{0,593}, \quad (40)$$

$$\text{Re}_g = \frac{v_g \delta}{\nu_g}, \quad (41)$$

$$Gm = \frac{g \delta^3}{\nu_g^2}, \quad (42)$$

where Re_g – Reynolds number characterizing the process of interaction of the particles of the liquefied medium with the incoming air;
 Gm – dimensionless complex.

The Reynolds number characterizing the process of formula (44) includes the characteristic air velocity, for which it is recommended to use the following dependences when considering the processes occurring in the layer [15]:

$$\tilde{q} = v_g F_g \varepsilon_u, \quad (43)$$

$$\varepsilon_u = 1, 2 \varepsilon_* \left(\frac{v}{v_*} \right)^\theta, \quad (44)$$

$$\theta = 0,08 + 4 \cdot 10^{-8} a_0 Gm, \quad (45)$$

$$a_0 = \frac{\rho_0 - \rho_g}{\rho_g}, \quad (46)$$

where \tilde{q} – volume flow rate of air supplied to the soil, m^3/s ;

F_g – the characteristic area on which the air from the nozzle head liquefies the soil layer, m^2 ;

ε_u – effective porosity of the soil layer;

ε_* – effective porosity of the soil layer at the initial moment of liquefaction;

v_* – air velocity, providing the beginning of liquefaction, m/s ;

θ – exponent;

a_0 – the Archimedes parameter for an amber-containing soil particle in the air supply.

The results of the calculations performed by the formula (45) show that the values of the density and particle size of the skeleton of the sandy-clay mixture under study, without losing the accuracy of the value of the exponent θ can be considered equal 0,08.

Based on this, using the results of experimental studies on the measurement of the density of the soil layer containing particles of amber under hydromechanical action with and without air supply, the dependence (44) can be rewritten as follows:

$$\varepsilon_u = \varepsilon_w \left(\frac{\tilde{q}}{\tilde{q}_w} \right)^{0,08}, \quad (47)$$

where \tilde{q}_w – characteristic air supply, $\tilde{q}_w = 0,000217$.

To estimate the characteristic area on which the air from the nozzle head liquefies the soil layer, we will use recommendations for choosing the geometric parameters of the probe used for direct impact on the soil, in particular, the estimate of the distance between adjacent rods [10, 15, 24, 29]. Assuming that the air exiting the nozzle liquefies the soil to a volume limited by two axial cylinders. The outer cylinder radius is equal to this value and the inner cylinder radius is equal to the radius of the bar. In this case, the value F_g can be determined from the following formula [15]:

$$F_g = \pi t g \phi \left(\frac{d_T}{h_{dd}} + t g \phi \right) h_{dd}^2, \quad (48)$$

where ϕ – the taper angle of the nozzle through which air is supplied;

d_T – the diameter of the bar on which the attachment is attached, m ;

h_{dd} – length of the conical part of the working body, m .

Substituting formulas (44) - (48) into expression (43), after performing all the transformations taking into account (39) - (43), we obtain the following dependencies for determining the value σ :

$$\sigma = k_\sigma \frac{\sqrt{1-\varepsilon}}{\rho z^{1,3}}, \quad (49)$$

$$k_\sigma = K \left(\frac{\rho_g}{\rho_s} \right)^{0,593} Gm^{0,735} \Delta^{0,407} \frac{\varepsilon_w^{1,414}}{1,45}, \quad (50)$$

$$K = \left(\frac{\sqrt[3]{g v_g h_{dd}^2}}{1,37 \tilde{q}_w} \right)^{1,414}, \quad (51)$$

$$z = \frac{\tilde{q}}{\tilde{q}_w}, \quad (52)$$

where K – dimensionless technological constant;
 z – dimensionless air flow.

Thus, a joint consideration of formulas (32) - (34), (10), (11) and (49) - (52) gives us the following dependencies for determining the rate of emergence of an amber particle under hydromechanical action on a water-sandy massif:

$$Re = \frac{w}{\Delta^{0,407} \varepsilon_w^{1,414}} \frac{(1-\varepsilon)\Delta-1}{\sqrt{1-\varepsilon}} z^{1,3}, \quad (53)$$

$$Re = \frac{v d}{v_g}, \quad (54)$$

$$w = \frac{1-f}{13,45 K} \left(\frac{\rho_s}{\rho_g} \right)^{0,593} \left(\frac{d}{\delta} \right)^3 Gm^{0,265}, \quad (55)$$

where Re – Reynolds number, which characterizes the process of the emergence of amber particles through a vibrating pneumatic fluid medium.

It is convenient to rewrite the right part of expression (53) in the following form, bringing the two terms in the numerator and denominator to the same form

$$\frac{Re}{W} = \frac{1-n\varepsilon}{\sqrt{1-\varepsilon}} z^{1,3}, \quad (56)$$

$$W = w \frac{\Delta-1}{2,2 \Delta^{0,407} \varepsilon_w^{1,414}}, \quad (57)$$

$$n = \frac{\Delta}{\Delta-1}. \quad (58)$$

Given that the value of soil porosity in hydromechanical impact is subject to the following restriction from above

$$\varepsilon < 1, \quad (59)$$

then, based on the rules of representation of functions of this kind in power series, the dependence (56) can be rewritten as follows (Fig. 3): then, based on the rules of representation of functions of this kind in power series, the dependence (56) can be rewritten as follows (Fig. 3):

$$U = \left(1 - [\gamma + \beta z + \alpha z^2] \varepsilon_\omega\right)^m z^{1,3}, \quad (60)$$

$$U = \frac{\text{Re}}{W}, \quad (61)$$

$$m = \frac{1}{2} \frac{\Delta + 1}{\Delta - 1}. \quad (62)$$

Fig. 3. Dependency graphs U from dimensionless air flow at different oscillations of the working body.

From Fig. 3 it is seen that the obtained dependence of the dimensionless velocity of the particles of amber on the dimensionless flow rate (60) has a maximum in the range of values of air flow close to the experimentally obtained value, in the vicinity $q = 0,015 \text{ m}^3/\text{h}$, which depends on the frequency of oscillation of the working body, similar to the results obtained in laboratory and field experiments [29].

Comparison of the results of the formulas (60) made for the frequency of 30 Hz with the results of experimental laboratory studies shows a satisfactory coincidence of the results of the calculations and experiments in the area $q = 0,015 \text{ m}^3/\text{h}$ (Figs. 4, 5). Thus, in the volume flow rate range from 0,014 to 0,025 m^3/h , the relative error of calculations does not exceed 10%.

Fig. 4. Dependence of the amber particle floating rate on the air volume supplied at a 30 Hz oscillator.

Fig. 5. Comparison of the results of calculations and experiments at the oscillation frequency of the working body of 30 Hz (error of calculations does not exceed 10%).

3.2 Determination of the rational parameters of the process of hydromechanical extraction of amber from sand deposits

The study of the dependence (60) on the extreme, by approximating the first derivative in magnitude to zero, indicates the existence of a maximum of the function under study at the following value of dimensionless air flow:

$$z_{\max} = \sqrt{A^2 \left(\frac{\beta}{2\alpha}\right)^2 + B \frac{1 - \varepsilon_\omega \gamma}{\varepsilon_\omega \alpha}} - A \frac{\beta}{2\alpha}, \quad (63)$$

$$A = \frac{1,3\Delta - 0,8}{2,3\Delta - 0,3}, \quad (64)$$

$$B = \frac{1,3(\Delta - 1)}{2,3\Delta - 0,3}, \quad (65)$$

where z_{\max} is the value of dimensionless air flow at which the maximum velocity of the particles of amber is realized.

Substituting expression (63) into formula (60) and performing the corresponding transformations and erections of such terms, we obtain the following dependence for determining the maximum rate of emergence of amber particles under hydromechanical action on the water-sandy massif:

$$\text{Re}_{\max} = W_\Delta (z_\omega - z_{\max})^m z_{\max}^{1,3}, \quad (66)$$

$$z_\omega = \frac{1 - \gamma \varepsilon_\omega}{\varepsilon_\omega \beta} \frac{\Delta + 1}{\Delta + 0,5}, \quad (67)$$

$$W_\Delta = w \frac{\Delta - 1}{\Delta^{0,407}} \left(\frac{\Delta + 0,5}{2,3\Delta - 0,3}\right)^m \varepsilon_\omega^{m-1,414} \beta^m. \quad (68)$$

Comparison of the results of formulas (63) and (66) performed for the frequency of 30 Hz with the results of experimental laboratory studies shows sufficient accuracy for engineering calculations and: relative error for air flow does not exceed 11,3% (calculation – 0,0133 and fact – 0,015 m^3/year); and for the maximum velocity of the particles of amber is 32,5% (the calculation is 0,053 and the fact is 0,04 m/s). The high error in

determining the maximum floating velocity can be explained by the significant dependence of this value on the particle size of the amber and the skeleton of the water-saturated soil, which varied during the experimental studies at fairly wide intervals.

Comparison of the results of the calculations according to formula (63) with the results of other authors [2-9, 15, 17-29] (Figs. 6, 7) confirms the reliability of the proposed dependence obtained for laboratory studies at a frequency of 30 Hz (Fig. 8, 9).

Fig. 6. The dependence of the air flow rate, which provides the maximum flow rate of the amber particles obtained by calculation (63) and according to experiments, from the frequency of oscillation of the working body.

Fig. 7. The dependence of the maximum rate of emergence of amber particles obtained by calculation (63) and according to experiments, on the frequency of oscillation of the working body.

Fig. 8. Comparison of the results of the calculations by (63) and the experiments to determine the air flow rate, which provides the maximum velocity of amber particles (relative error does not exceed 11,3%).

Fig. 9. Comparison of the results of the calculations for (63) and experiments to determine the maximum rate of emergence of amber particles.

The results of the numerical analysis of the terms on the right-hand side of formula (63) indicate that it is possible to use for engineering calculations the air flow rate, which provides the maximum velocity of the particles of amber, the following simplified dependence:

$$z_{\max} = 0,008 \frac{\Delta^{0,281}}{\sqrt{\varepsilon_{\omega}}} \quad (69)$$

Joint consideration of formulas (66) - (69), with preliminary approximation of complexes depending on the value Δ degree functions, allows you to propose the following simplified dependence for engineering calculations of the maximum velocity of the particles of amber floating:

$$Re_{\max} = \frac{w \gamma^m \Delta^{1,86}}{500 \varepsilon_{\omega}^{2,064}} \quad (70)$$

Conclusions

Studies have shown that the maximum possible rate of emergence of amber in hydromechanical extraction of sand deposits is directly proportional to the square of the diameter of the particles of amber and the medium, and inversely proportional to the square of the porosity of the soil, which arises from the oscillation of the working organ 20 to 35 Hz without air supply, and its dependence on the density ratio of the soil particles and the material extracted is described by a power function with a positive fractional index of 1,86.

The analytical results obtained confirm the experimental data quite accurately, which allows us to use them in the future for engineering calculations. The obtained expressions will allow with sufficient accuracy to calculate the parameters of the process of extracting amber from amber-containing deposits, as well as to set the parameters of technological equipment for the implementation of this process.

Abstract. A method for optimizing the protecting pillars parameters during the study of soft enclosing rocks (in Ukraine mines) is represented. The necessity of a differentiated approach has been substantiated when choosing the protecting pillar parameters based on the geomechanical factors analysis influencing the state of massif. Mining and geological situation was analysed. It has been studied a stress-strain state (SSS) along the protecting pillar width with account of the mined-out space on the basis of a computational experiment and is presented in the form of curves of vertical and horizontal stresses distribution, as well as stresses intensity distribution. The recommended engineering decisions have been substantiated and the SSS of fastening and security structures has been analysed. A certain reserve of the fastening structure load-bearing capacity as part of the frame support and the combined roof-bolting system has been revealed. An evidence base has been created for the measures development on conducting and maintaining mine workings in the zone of the stope works influence. The recommendations have been developed on the protecting pillar formation with a width of at least 40 – 45 m to exclude the stope works influence.

1 Introduction

At present, there are trends to drive out the hydrocarbons from use in the energy sector. But, according to long-term predictions, the volumes of coal output will grow to 2040 by 20% from 7.7 to 9.23 bill t. The data presented in the work [1], show the presence of a positive attitude to the coal industry development in Ukraine. Coal is the only energy raw material, the reserves of which are potentially enough to ensure the energy security of our state and promote the development of the metallurgical and chemical industries. If in the structure of world reserves of the organic fuel main types, coal is 67%, then in Ukraine – 95.45% [2].

The necessity to introduce innovative coal technologies into production has a political, social-and-ecological, as well as economic basis.

One of the resource-saving trends in extraction of mineral resources is the optimization of the protecting pillars parameters, in which up to 70% of standard quality coal reserves are concentrated in exploited fields. This problem is complex to solve at the Western Donbas mines that is explained by specific mining and geological conditions [3, 4]. Coal in this region is hard enough (hardness coefficient according to M. M. Protodiakonov $f=2.0-3.5$), and the enclosing rocks – argillites, siltstones and sandstones are weakly stable ($f=0.8-2.5$). Therefore, when conducting the work, decisions were made to leave the pillars with large width [5].

The operational state of mine workings depends on

measures aimed to protect them from the rock pressure manifestations, which are provided for at all stages of the mine working existence: design, construction, operation, and abandonment [6, 7]. Unfortunately, the planned and implemented measures sometimes do not make possible to maintain a stable state of mine working [8, 9]. On the other hand, the experience of coal mining enterprises exploitation indicates the situations arising where, according to well-founded design decisions, the stability of mine workings is excessive and is ensured by the unnecessary waste of resources, primarily mineral resources, for example, within natural protecting objects, the so-called pillars. Such pillars enable to protect mine workings, and the mineral resources loss within the entire mine reaches 10% or more of the mine's total reserves. That is why, determining the geometric pillars dimensions is an important and urgent task, the solution to which will reduce losses, increase output and optimize the coal product costs [10, 11].

The group of pillars is of particular interest, designed to ensure the stability of inclined overburden workings. This group includes, first of all, slopes and gravity inclines, of which should be 3, when uncovering the panel: slope (gravity incline) and two passage ways, between which there are pillars preventing the mutual influence of these mine workings. In addition, there are also pillars, the purpose of which is to protect the complex of mine workings from the bearing pressure influence at the front of the stope works. The width of such pillars with increasing depth of mining reaches 150 – 200 m [12], which, of course, leads to significant

* Corresponding author: kovalevska_i@yahoo.com

losses of coal reserves prepared actually for mining.

Thus, the development of a methodology for a possible reduction in the protecting pillars width is an urgent applied research task, which is important for the mining industry. The second solution component to this problem is the substantiation of resource-saving technologies for fastening and maintaining mine workings in the zone of the stope works influence.

2 Research methodology, analysis of mining-geological and mining-engineering conditions

The problem of optimizing the protecting pillar width was solved using the example of “Dniprovsk” Mine of Dniprovsk Mine Group, DTEK “Pavlohraduhillia”, PRAT. The plans for mining operations development along the seam C_{10}^I in “Dniprovsk” Mine provide for the further development of the North Drain Slope (NDS) to the width of two extraction sites: the 1100 longwall face will be mined-out in 2020, the extraction of reserves at the 1001 longwall face will be completed in 2021. To ensure the two indicated mining sites operation, in 2019 it is planned to develop the NDS to the area of entry to the 1100 prefabricated drift, and in 2020 – until junction with the 1101 prefabricated drift.

The NDS protection from the stope works influence in the 1100 and 1001 longwall faces is provided by trapezium-shaped coal pillars, in which the minimum distance L_{pr} from the face entry to the NDS is 85 – 90 m. According to the normative documents on the mine workings location, such a width of the protecting pillar should be sufficient to maintain the NDS of the seam C_{10}^I in a satisfactory state for the entire period of its exploitation. On the other hand, the experience of mining operations in the Western Donbas indicates the ambiguity of the link between the protecting pillar width and stability degree of the main preparatory mine workings [13]: their state is enough satisfactory (in accord with safety standards and rules) with a protecting pillar width of several tens of meters. On the contrary, the case when they are protected by a coal pillar with a width of about 200 m and sometimes even more does not meet the requirements for safe operation. Obviously, a differentiated approach is required when choosing the protecting pillar width, based on the analysis of geomechanical factors influencing the massif state in the location area of a newly constructed NDS site of the seam C_{10}^I . Thus, the task of research is to study the possibility of reducing the protecting pillar width along with the measures development on conducting and maintaining the NDS of the seam C_{10}^I , taking into account the influence of the rock pressure anomalies during mining of the 1100 and 1001 longwall faces.

In accordance with the plan of mining operations development (Figure 1), at this mine field site, the depth of placement of the constructed NDS site of the seam C_{10}^I is $H = 420 - 450$ m, and tectonic disturbances can occur along the trace of mine working. According to Geological Survey data of “Dniprovsk” Mine, complex mining-geological and hydrogeological conditions are

expected when developing the NDS of the seam C_{10}^I , which are conditioned by several factors. Firstly, mine working crosses two dangerous areas.

Secondly, the immediate bottom rocks of the coal seam C_{10}^I represented by siltstone, are characterized by low strength characteristics, and when being moistened, they are prone to soaking and heaving [14].

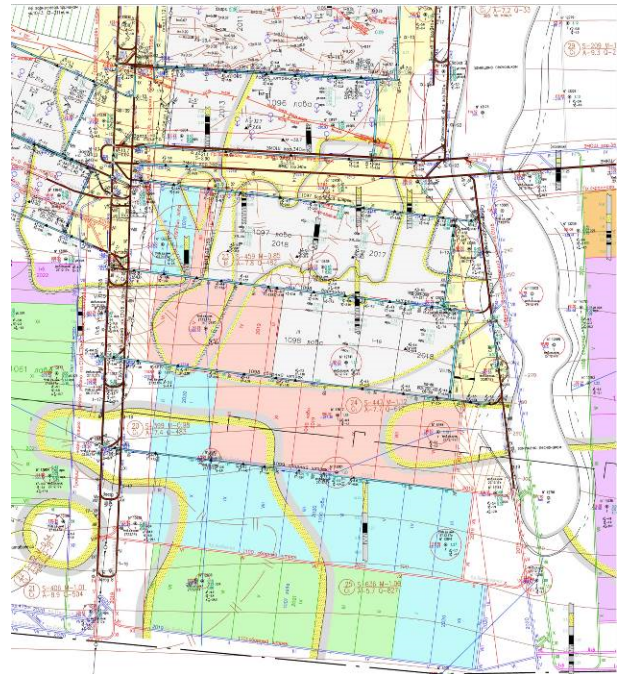

Fig. 1. Excerpt from the plan of mining operations along the seam C_{10}^I of “Dniprovsk” Mine along the NDS trace in the area of the planned 1100 and 1001 longwall faces.

Thirdly, the water-cut of mine working is conditioned by the sandstone occurring in the main roof and coal seams C_{10}^I and C_{10}^{II} , as well as the possible water ingress in the crossover point of the tectonic disturbances of “fault” pattern [15]. The expected water inflow in the face space is 1.5 – 6.0 m³/h, and with long stops, an increase is possible of up to 10 m³/h. Furthermore, an additional water inflow will be formed from the 1097 prefabricated drift, 1097 boundary drift, 1098 prefabricated and 1099 prefabricated drifts, which in total will increase water inflow through the NDS of the seam C_{10}^I up to 25 m³/h.

The North Drain Slope of the seam C_{10}^I will be developed along the coal seams C_{10}^I and C_{10}^{II} , as well as along the rocks of their roof and bottom, represented by argillite, siltstone and sandstone, which occur at an angle of 3 – 6° in the north-east direction.

The stability of the enclosing massif and the preliminary prediction of rock pressure manifestations were assessed based on the geological sheet along the NDS of the seam C_{10}^I 265 m horizon (Figure 2).

The coal-bearing stratum geology at the newly constructed NDS site of the seam C_{10}^I has been studied in two directions:

- the area of the bearing pressure propagation in the protecting pillar during mining out the 1100 and 1001 longwall faces;
- assumed rock pressure manifestations around and

on the SDS contour to substantiate its fastening scheme.

At the first site of the mine working length, the following peculiarities of the coal-bearing stratum state are predicted.

The immediate roof of the seam C_{10}^I , represented by argillite with a thickness of 1.2 m, is characterized by an increased tendency to cleavage and collapse, despite the mean lithotype hardness (uniaxial compression resistance in the sample $\sigma_{compr} = 20.6 - 21.5$ MPa). The unstable state of immediate roof (when it is outcropped) is determined by two reasons. The first reason is a very low argillite adhesion to the coal seam C_{10}^I and the overlying sandstone. The second reason is that both of these lithotypes are water-flooded and the small argillite thickness causes its intense water saturation throughout the entire volume with a loss of hardness at least twice according to [16].

Fig. 2. Predictive geological sheet along the NDS of the seam C_{10}^I 265 m horizon.

Weak resistance of the immediate roof plays an ambiguous role in the issues under study. From the point of view of the bearing pressure formation in the protecting pillar, the weak, easily deformable and weakened immediate roof functions as a damper, partially smoothing out the stresses concentrations in the area of the border with the mined-out space. On the other hand, it is possible to unambiguously predict argillite collapse throughout entire its thickness over the NDS arch, which forms a relatively small vertical and oblique load on the mine working support.

The adjacent two layers of the main roof are represented by sandstone with a thickness of 1.6 m and argillite with a thickness of 2.0 m. The sandstone is

water-flooded and loses its hardness from 20 to 40% [16] with its rather mean compressive resistance in the sample $\sigma_{compr} = 11.7 - 53.3$ MPa. Argillite is not hard ($\sigma_{compr} = 7.7 - 26.4$ MPa), and with partial moistening of its lower part from the water-bearing sandstone, it can be considered a weak unstable lithotype. Moreover, the adhesive forces on the bedding surfaces are very low, and with horizontal shifts (for example, in the bearing pressure zone), the contacts are completely disturbed. Above siltstone occurs, divided by an interlayer of limestone (with a thickness of 0.4 m) into two parts: lower – with a thickness of 5.7 m with $\sigma_{compr} = 23.5 - 29.7$ MPa; upper – with a thickness of 6.7 m with $\sigma_{compr} = 12.0 - 34.1$ MPa. With a relatively mean hardness and a predominantly naturally moist state of siltstone, its behaviour can be assessed as a quite stable due to the increased thickness.

The roof rocks composition is described to a height of 17.6 m; the overlying lithotypes, according to the existing concepts [10, 11], will be deformed (during the stope works operations) without discontinuity, although it is likely that thick siltstone layers will be resistant even when partially divided into blocks due to formation of thick thrust-block systems. In the lower part of the main roof, weakened sandstone and argillite with a medium thickness will definitely collapse into the mined-out space, and the rock cantilevers, hanging from them, have a small length. Both above factors facilitate the formation (at the mined-out space boundary) of the bearing pressure zone with a low stresses concentration, which will decrease when moving backward into a virgin massif in the direction of the NDS of the seam C_{10}^I . Around the mine working itself, the weakened rocks border area formation is possible, since sandstone and argillite in the roof are not sufficiently stable.

The following lithotypes are located in the sides and the bottom of the NDS of the seam C_{10}^I : the coal seam itself is quite hard ($\sigma_{compr} = 40.0 - 50.0$ MPa), but fractured and water-flooded with weakened contacts along the bedding planes; in the immediate bottom, siltstone with a thickness of 1.3 – 1.8 m, most likely water-flooded with $\sigma_{compr} = 15.6 - 24.1$ MPa; in the main bottom, argillite occurs, divided by the coal seam C_{10}^{II} into two layers with $\sigma_{compr} = 10.0 - 33.2$ MPa. The indicated massif structure in the sides and the nearest layers of the mine working bottom suggests the development of an increased lateral bearing pressure onto the support, and the bottom water-cut provokes its intense heaving [17, 18]. The so-called “stamp effect” should be added to this [19], when a harder coal seam presses-out (due to an increased vertical pressure) the less hard and easily deformable underlying rocks into the sides and the bottom of mine working.

Therefore, the following preliminary conclusions can be made at the first site of the dangerous zone:

- in a coal protecting pillar, in the area of the border with the mined-out space, the bearing pressure zone will be characterized by reduced stresses concentrations;
- a differently vectored rock pressure will be formed around the NDS of the seam C_{10}^I with different intensity of the border rocks displacements in the roof, sides and bottom of mine working;

- development of an unstable state of argillite and sandstone to a height of up to 4.8 m is possible in the roof of the NDS of the seam C_{10}' , but it can be dramatically restricted by applying the combined roof-bolting systems [20 – 22], with which the vertical and oblique load in the arch will decrease to safe values;

- an increased lateral load on the prop stays of the frame support is predicted in the sides of mine working, and to maintain their stable shape, it is proposed to set the lateral roof-bolts with their tail joints connected with the prop stays of the frame by means of pliable (rope) binders [23];

- an intensive heaving is supposed in the bottom of the NDS of the seam C_{10}' , which is partially restricted by lateral resin-grouted roof bolts, and the main method to resist to heaving is the same – periodic bottom rocks ripping.

At the second site of the NDS length of the seam C_{10}' , similar rock pressure manifestations are predicted, but there are some peculiarities.

The first peculiarity is connected with a change in the lithology of the seam C_{10}' roof rocks and the deviation of mine working into its bottom. Now, a layer of siltstone with a thickness of 1.5 – 1.8 m is located above the mine working arch, and beginning with PK61, an interlayer of argillite with a thickness of 0 – 0.6 m appears directly on the contour as a kind of friable roof by analogy with the stope faces. The average compressive resistance of siltstone in the sample is 19.9 MPa, argillite – 21.6 MPa. Both lithotypes are of medium-bedded stratification and their water saturation from the seam C_{10}' is predicted. For this reason, an unstable state of border rocks should be expected in the NDS roof to the thickness height of siltstone and argillite. The coal seam C_{10}' , despite its relative hardness, is water-flooded and fractured; therefore, it can be classified as weakly stable. The argillite of the immediate roof of the seam C_{10}' with a thickness of 2.0 – 2.6 m is water-flooded, hence, it is difficult to express an unequivocal opinion in terms of its stability. The first layer of the main roof is represented by sandstone with a thickness of 2.4 – 3.0 m with an average compressive resistance of 32.5 MPa, and despite its water-cut, the lithotype can be assessed as stable.

Thus, formation of a vast region of unstable rocks up to 6.0 m high over the NDS arch of the seam C_{10}' is possible, which is able to form a vertical and oblique load of a dangerous value.

From the point of view of the protecting pillar state at the border with the mined-out space, an attention should be paid here to the change in the composition of the main roof rocks of the seam C_{10}' . There partial replacement occurs of siltstone with argillite and two lithotypes with medium thickness are formed (1.6 m and 1.8 m, respectively). Hard limestone is located above ($\sigma_{compr} = 94.3 - 133.0$ MPa), but its low thickness (up to 0.8 m) and fracturing indicate weak stability. The total thickness of the described lithotypes is up to 12.0 m and a variant of roof stratifications development to such a height is quite possible. The variant of the hinged-block displacement zone extension through the thickness (6.4 m) of the overlying siltstone up to a coal interlayer with a thickness of 0.1 m is less possible. Nevertheless,

in both cases, the structure of the roof rocks of the seam C_{10}' can be characterized as predominantly medium-bedded, with the rock cantilevers insignificantly overhanging into the mined-out space. Therefore, moderate stresses concentrations in the bearing pressure zone of the coal pillar should be predicted.

The second difference of the studied dangerous zone is a change in the rocks structure of the seam C_{10}' bottom. Here, throughout the mine working height, mainly thin layers of argillite and siltstone are located, as well as coal seam C_{10}'' with a two-band structure. With a relatively insignificant hardness, all lithotypes are water-flooded, which, with a significant geostatic pressure ($H = 420 - 450$ m), predicts the formation of large areas of weakened rocks in the NDS sides, as well as the development of a significant lateral load onto support.

The NDS bottom of the seam C_{10}' is represented by a thick (9.3 m) siltstone with an average compressive resistance in the sample of 19.9 MPa. The siltstone stratification and a probability of water saturation of its upper bands suggest the development of heaving process from moderate to intense. However, in the mine working sides, there is no sufficiently rigid lithotype, and the existing thin and weakened lithological varieties are not able to create a “stamp effect”. Therefore, it is expected that the predicted heaving will be of moderate value.

Summing up the analysis results of mining and geological situation as a whole around the NDS sites of the seam C_{10}' , constructed according to the plan of mining operations, a preliminary assessment should be made:

- moderate stresses concentration in the bearing pressure zone along the protecting pillar width in the border area with the mined-out space is unlikely to influence the mine working state, and the possibility of reducing the protecting pillar width will be substantiated below when performing a computational experiment;

- it is predicted the development of differently vectored rock pressure manifestations on the mine working contour and it is recommended to use various engineering decisions to ensure its stability, in particular, combined roof-bolting systems and the structural coupling of lateral resin-grouted roof bolts with the prop stays of the frame support.

3 Substantiation of the possibility to reduce the protecting pillar width

A preliminary expert assessment of the coal-bearing massif state in the boundary area of the protecting pillar of the SDS of the seam C_{10}' and the mined-out space, when the 1100 and 1001 longwall faces move backward from the face entry, indicates the low stresses concentration in the bearing pressure zone. The reason for this statement was revealed in the works [21, 22, 25]: easily deformable and relatively weak layers of the roof are not able to form any stretched rock cantilevers on the border of the mined-out space, which concentrate the bearing pressure near the protecting pillar border; low deformation characteristics of lithotypes (caused by discontinuity, stratification and water-cut), due to

damping properties, localize the high rock pressure (HRP) areas at a limited coal pillar length; hence, the stope works influence in the 1100 and 1001 longwall faces does not extend in a protecting pillar to remote areas, including the area where the NDS of the seam C_{10}^I is located.

The above representations have been tested by means of a computational experiment using proven techniques [18, 23, 26-28] as applied to the analysed mining and geological conditions. Taking into account the need to consider the complex of geomechanical and mining factors a conclusion about feasibility of modern computer programs by the FEM use is obvious for the solution of set problems: models creation – *Solid Works* program, the SSS calculation of the system elements in elastic approach – *Desain Star* application; materials anisotropy consideration – *Cosmos-M* program, wide opportunities of *Ansys* complex. The computational experiment results are presented in the form of curves of vertical σ_y , horizontal σ_z and intensity σ stresses distribution along the protecting pillar width z , including the mined-out space to a length approximately twice the step of primary setting of the main roof.

Analysis of the vertical stresses σ_y curve (Figure 3) has revealed the following results.

Fig. 3. The vertical stresses σ_y distribution across the protecting pillar width.

The dimensionless indicator K_y is the most informative parameter, which determines the effective value σ_y relative to geostatic vertical pressure γH of virgin massif (as denoted here: H – depth of mining operations; γ – weight-average unit specific gravity of rocks in the coal-overlying formation). The second indicator is the distance $l_{y,z}$ of a specific concentration value K_y distribution into the roof and bottom of the seam C_{10}^I (distance l_y) and across the protecting pillar width (distance l_z).

In full compliance with existing concepts, the highest concentrations of K_y were recorded near the protecting pillar border, adjacent to the mined-out space of the 1100 and 1001 longwall faces; the maximum distances $l_{y,z}$ of each discrete value propagation K_y are also noted here. Thus, the concentrations of $K_y \geq 2.0 - 2.5$, capable of weakening the lithotypes of the coal-bearing stratum, develop into the seam C_{10}^I roof to a height of up to 1.8 m; into the bottom – to a depth of 1.6 m; across the pillar width $l_z = 3.5 - 4.0$ m and capture the immediate roof rocks, and in the coal seam itself, the local areas are observed at a distance of up to 3.0 – 3.5 m; the greatest distance l_z to 5.0 is recorded in the immediate bottom

rocks. The next category of vertical stresses concentration $K_y = 1.5 - 1.8$ is able to partially weaken the rocks of the immediate roof and bottom, taking into account their probable water saturation, but the harder lithotypes (coal seam C_{10}^I and sandstone of the main roof) retain their continuity and are capable of further resistive action to vertical rock pressure. The width of the partial weakening area is up to 8–9 m in the immediate roof, and up to 10 – 12 m in the immediate bottom.

The concentration level $K_y \leq 1.5$ has the largest propagation area, in which the lithotypes of the adjacent coal-bearing stratum mainly retain their natural structure, and some local discontinuity is conditioned by water saturation, stratification and fracturing of the weakest rock layers – siltstone and argillite of the immediate bottom. As for the argillite of the immediate and main roof (occurring in the dangerous zone), the following situation is predicted here in the area of the protecting pillar with a width $l_z \leq 8.0$ m.

It was previously noted that the immediate roof is definitely weakened, and the water-flooded sandstone remains continuity at $l_z \geq 3.5 - 4.0$ m. But the second layer of the main roof, occurring above sandstone, is exposed to partial water saturation, and its separate samples (when tested for compression) have shown very low values of $\sigma_{compr} = 7.7$ MPa. Such compressive resistance, even with $K_y < 1.5$, presumes argillite weakening of the main roof second layer to a coal pillar width of up to 8.0 m. Argillite with the same strength properties is the fourth layer of the main roof, located at a height of about 10 m from coal seam C_{10}^I . At this height,

a concentration of $K_y = 1.5$ is localized and is not propagated further. However, it is necessary to take into account a sufficiently large (for the Western Donbas conditions) depth of $H = 420 - 450$ m of mining operations and here the geostatic pressure, even at low concentrations $K_y = 1.2 - 1.3$, can partially weaken the separate argillite bands with $\sigma_{compr} = 7.7$ MPa. Therefore, it is quite predictable a formation of the weakly stable rocks area (in the dangerous zone) to a height of 12 – 13 m, where a thin limestone layer occurs.

This conclusion refers only to a border area of the protecting pillar with a width of up to 4.0 m, but in weak argillite layers of the main roof it can be propagated over a width $l_z = 10 - 13$ m. Further into massif, the vertical stresses concentrations dramatically decrease, which reflects the following parameters:

- at a distance $l_z = 30 - 32$ m, insignificant concentrations of $K_y = 1.2 - 1.3$ level completely disappear in the main roof and its state is determined by the geostatic pressure of virgin massif; that is, at such a distance, the stope works influence is absent;

- in the immediate roof and the first layer of the main roof, the increased concentrations of $K_y = 1.5 - 1.8$ level are propagated locally to a distance of $l_z = 22 - 27$ m mainly due to the sandstone tensile strain;

- in the coal seam C_{10}^I , due to its increased rigidity, the concentrations of $K_y = 1.8 - 2.0$ are acting up to the level of $l_z = 18 - 22$ m; for the same reason, the stope works influence in the immediate bottom can be

observed up to $l_z = 22 - 24$ m.

With further removal from the boundary of mined-out space, its influence on the of vertical stresses σ_y distribution disappears – the protecting pillar itself and the coal-bearing stratum approach to the state of a virgin massif.

Thus, according to the factor of the component σ_y action, the absence of the stope works influence in the 1100 and 1001 longwall faces at a distance of more than 32 m from the face entries has been proved. Therefore, with a certain safety factor of the prediction, it is quite expedient to leave the coal pillar with a width of 40–45 m for the protection of the NDS of the seam C_{10}' .

This conclusion has been tested by means of analysing the curve of the horizontal stresses σ_z distribution across the protecting pillar width z and the stresses intensity σ , confirming the conclusions on vertical stresses.

Given a similar influence according to the action factors of vertical stresses σ_y , horizontal stresses σ_z and stresses intensity σ , it can be considered reasonable to make an engineering decision on the NDS protection of the seam C_{10}' by a coal pillar with a width of 40 – 45 m.

4 Measures development on conducting and maintaining the NDS of the seam C_{10}' in the zone of the 1100 and 1001 longwall faces influence

The measures to conduct and maintain the NDS of the seam C_{10}' have been developed on the basis of scientific research and practical experience of the mine workings exploitation in the mining and geological Western Donbas conditions [3, 4, 19]. Earlier, the possible rock pressure manifestations has been preliminary assessed and general recommendations for ensuring the stable state of the NDS of the seam C_{10}' has been made.

In this chapter, the recommended engineering decisions have been substantiated, including application of the method of computational experiment.

In the previous studies, a system of evidence was given that there is no stope works influence in the 1100 and 1001 longwall faces with a protecting pillar width of 40 – 45 m. Here, substantiation is continued of absence of the stope works influence, based on the implementation of the following algorithm of actions.

Firstly, the main negative factors were distinguished earlier that (according to preliminary expert assessment) can significantly influence on the SDS stability of the seam C_{10}' in the area of the 1100 and 1001 longwall faces location:

- possible asymmetry of the load on the mine working fastening structure needs to be tested by determining the SSS of the maintenance scheme main elements;

- there is a probability of arising an extensive arch of ultimate equilibrium around the NDS, which is able to form a high vertical and oblique load from the side of the roof rocks; the SSS analysis is required here of the previously recommended fastening structure in terms of effectiveness of its resistive action to rock pressure;

- an increased lateral load development on the fastening structure is possible – to check this, it is necessary to study the SSS of the prop stays of the frame support: assess the probability of their plastic bending.

Secondly, the measures substantiation to maintain the NDS of the seam C_{10}' is performed on the fastening structure model, which is called “experimental” for the following reasons:

- to resist to vertical and oblique rock pressure, the frame support of TSYs series is strengthened by a combined roof-bolting system according to the recommendations [29, 30] of the resin-grouted roof bolts and rope bolts arrangement;

- a central prop stay of the strengthening support is set in the frame arch to control the danger level of the vertical and oblique loads development; it performs the functions of a “detector”, which assesses the degree of its loading, the sufficiency of the used fastening elements or the necessity to supplement them with other structures; in addition, according to arising bending deformations in the central prop stay of the strengthening support, the level of the vertical load asymmetry is determined, that is, indirectly, the degree of the stope works influence;

- more significantly, the influence degree of the stope works in the 1100 and 1001 longwall faces is assessed by the level of loading the second “detector” – of the lateral prop stay of the strengthening support, erected from the side of the coal pillar;

- the third “detector” is the prop stays of the TSYs frame support – according to the parameters of the stresses components distribution in them, the danger degree of plastic bending is determined, which serves as an indirect indicator of the lateral load value; then, the question should be solved, whether it is necessary to set (or not to set) the lateral resin-grouted roof bolts and strengthen the frame prop stays with the help of pliable binders with the roof-bolt tail joints.

The described methodological technique in the technology of performing the computational experiment enables, in our opinion, to solve all the tasks set for substantiating the measures to maintain the NDS of the seam C_{10}' in the zone of the 1100 and 1001 longwall faces influence.

The SSS study of each main fastening structure element is performed on the three most informative components: vertical stresses σ_y , horizontal stresses σ_z and stresses intensity σ .

A sequential analysis of the peculiarities of each component distribution has revealed that the vertical stresses σ_y curve, presented in Figure 4.

The first significant peculiarity of the curve σ_y is observed in the cap board of the frame support and characterized by its quite significant underloading (compared with the estimated yield limit σ_{yield} of the SCP steel), despite the action of stresses with different signs.

The revealed situation with a very low loading of the frame cap board can be explained by three reasons:

- low vertical and oblique load from the limited dimensions of the arch of ultimate equilibrium;

- high reaction of the central and lateral prop stays of the strengthening support, which unloads the frame cap

board;

- efficient performance of the combined roof-bolting system to create an armoured and rock plate with high load-bearing capacity.

The second peculiarity of the curve σ_y is the combination of a significant loading of the frame prop stays with a relatively uniform distribution of σ_y in the SCP cross section.

Fig. 4. Curve of vertical stresses σ_y in the preliminary variant of fastening structure of the NDS of the seam C_{10}^I .

The above results make possible to draw the following conclusions. On the one hand, the frame prop stay experiences a significant vertical load, but within the permissible load-bearing capacity. This indicates the assumptions validity about the formation of an extensive arch of ultimate equilibrium. On the other hand, the frame prop stay copes with resistive action to lateral load, since there is practically no bending moment throughout its main height (about 80 – 85%); only in the bearing area of the prop stay, a bending moment acts with a value that is not dangerous from the point of view of its plastic bending. The latter circumstance indicates the inexpediency of hardening the NDS sides with the roof-bolts and strengthening the frame prop stays with pliable binders.

Similar result σ_y , in terms of quality, has also been obtained for the left frame prop stay, adjacent to the protecting pillar. Only here, the value of compressive stresses σ_y was 30 – 33% less than in the right frame prop stay, which is conditioned by the influence of the lateral wooden prop stay of the strengthening support.

From the third peculiarity of σ_y distribution, described above, the following conclusions can be drawn. Firstly, there are no bearing pressure effects in the protecting pillar (with a width of 40 m) on the increase in vertical load in the adjacent prop stay of the frame. On the contrary, the total resistance reaction of the lateral wooden prop stay and frame prop stay is

slightly reduced. Secondly, the lateral wooden prop stay is not only weakly loaded, but also does not experience any bending forces. This indicates the absence of increased rock pressure from the side of protecting pillar.

The fourth peculiarity of the curve σ_y relates to the central wooden prop stay of the strengthening support and reflects two facts: very low level of loading about 15 – 20% of the estimated load-bearing capacity value; practical absence of bending moment throughout the entire height. The first fact indicates that the frame support and the combined roof-bolting system quite cope with rock pressure: the central prop stay of the strengthening support is not necessary. The second fact notes the absence of any significant asymmetry in the fastening structure loading, and, consequently, the stope works influence through the protecting pillar.

Summing up the analysis results of the vertical stresses σ_y distribution in the fastening structure of the SDS of the seam C_{10}^I , it is necessary to highlight the following basic provisions:

- the fastening structure as part of the frame support of the TSYS series and the combined roof-bolting system resists to rock pressure with some reserve of load-bearing capacity;
- with the protecting pillar width of 40 m, the stope works influence in the 1100 and 1001 longwall faces is not revealed;
- the conclusions of the preliminary expert assessment were amended in terms of lack of the necessity to set resin-grouted roof bolts in the mine working sides and their connecting with the prop stays of the frame support.

The horizontal stresses distribution and the stresses intensity in the elements of the fastening structure supplement the earlier conclusions about its stability degree.

The almost complete absence of bending moment both in the prop stays of the frame (with the exception of an area of their bearings) and in the wooden prop stays of the strengthening support indicates the same absence of oblique load from the side of the coal pillar. It can be concluded from here that the width 40 m of the last excludes the stope works influence in the 1100 and 1001 longwall faces.

Assessing the degree of loading the roof bolts of the combined roof-bolting system, it should be noted that there is a reserve of load-bearing capacity of at least 30 – 35%, which is included into the safety factor of the recommended fastening structure.

Summing up the performed research results, it can be considered that the evidence base has been created for the measures development on conducting and maintaining the NDS of the seam C_{10}^I in the zone of the 1100 and 1001 longwall faces influence in “Dniprovsk” Mine.

5 Measures on conducting and maintaining the NDS of the seam C_{10}^I

To ensure a stable state of the North Drain Slope of the seam C_{10}^I for the entire period of its exploitation, the

following measures have been developed:

1. In order to exclude the stope works influence in the 1100 and 1001 longwall faces, planned by the time schedule, to form from their side a protecting pillar with a width of at least 40 – 45 m.

2. During the period of the new site development of the NDS of the seam C_{10}^I , apply the fastening structure, including the frame support of the TSYS series and the combined roof-bolting system in accordance with the scheme in Figure 5.

3. The frame support is set with a step of 0.8 m with a tightening of the interframe space by means of a cyclone fencing.

4. The combined roof-bolting system includes 6.0 m long rope bolts, being set in a chessboard pattern (with respect to the mine working sides) with a step of 3.2 m, as well as two pairs at a time resin-grouted roof bolts of 2.4 m long erected in the middle of the interframe space in each side with a step of 0.8 m.

5. To be actively engaged in the work to resist to the border massif stratification, the combined roof-bolting system is erected with the minimum possible (for technological reasons) lagging behind the drifting face.

Fig. 5. Scheme for the fastening structure of the NDS of the seam C_{10}^I .

The experimental and industrial testing of frame-roof bolt support with self-regulated load redistribution, has shown its high efficiency in terms of mine working sides displacements restriction. The mine working is in stable condition along the whole its extent, and displacements of rock contour are considerably lower than vertical and side constructive support yield.

6 Conclusions

Summing up the performed research results, it can be concluded about the methodology development for optimizing the protecting pillars parameters. Using the example of “Dniprovsk” Mine of DTEK “Pavlohraduhillia” PRAT and, with the application of the method of computational experiment, the possibility

of reducing the protecting pillar width has been proven. Based on the SSS analysis of the “massif – fastening system – protecting elements” system state, the measures have been developed on conducting and maintaining of mine workings in the zone of the stope works influence.

The authors express their gratitude to the management of DTEK Coal Unit for their help in organizing the experimental research.

³Karaganda State Technical University, Kazakhstan

Abstract. The paper discusses organizing online ore monitoring on process conveyor belts at the operations of Kazakhmys Corporation LLC using EDXRF method implemented as an ore-controlling station (OCS) targeting ore size of -300 mm. OCS is supposed to achieve the objective of providing reliable silver detection measurements in the range of 1+ ppm. Objects of monitoring: copper-containing polymetallic ores delivered to Zhezkazgan, Balkhash and Karagaily processing plants for treatment (target elements include copper, zinc, lead, silver, cadmium, and iron) as well as ores transported by the main underground feeder belt at Nurkazgan Mine (copper, zinc, lead, silver, molybdenum, and iron). The ultimate of the studies was to produce an online report on quality and quantities of ore and metals delivered from each of ore suppliers; to adjust the tonnages dispatched by the various shafts and open pits in the online mode; obtain reliable proof for unbiased redistribution of metals back to the mining operations. Equipment used during the studies: EDXRF OCS RLP-21T. Key features of the unit are also discussed. The results of bench-scale testing as well as industrial application of OCS RLP-21T are discussed leading to the conclusion of successful online monitoring of silver in ores sized from +1 ppm to -300 mm. The photographs were provided by S. A. Yefimenko.

1 Introduction

Pertinent issues in minerals mining include integrated mineral resource mining, underground resource reproduction, and maximum recovery of useful components during ore processing. Integrity of mineral use will radically reduce intensive technogenic environmental impact of mining operations and improve the geological and environmental conditions in Ukraine's industrial regions. Substantiation of efficient recovery of rare, valuable and noble metals in such minerals is an urgent problem for iron ore processing in Kryvyi Rih iron ore basin.

For example, ferruginous quartzites of Kryvyi Rih iron ore basin contain 0.114-0.3 g/t of gold. Gold occurs in the finely dispersed state in the form of elongated grains of $(3-15) \times 10^{-3}$ mm and plate aggregates with rounded edges in magnetite and in quartz.

Gold is found in low-grade magnetite ores of Kryvyi Rih iron ore basin and is unevenly distributed in different deposits. In the initial ore of Northern GOK, bound-state gold grades range from 0.016 g/t to 0.03 g/t, which was confirmed through mercury amalgamation studies detecting no free gold. In the south of Kryvyi Rih iron ore basin, the ore mined from Novo-Krivorozhsky and Ingulets GOKs has a somewhat higher average gold grade of 0.034-0.067 g/t, reaching 0.11-0.347 g/t in some areas.

Mineralogical studies have confirmed that free gold is contained only in ore sized less than $(8-10) \times 10^{-3}$ mm,

therefore less than 10% is disclosed. The remaining 90% of the total gold contained in the initial ore is dispersed in quartz and silicates, as well as in magnetite, carbonates and other minerals. Higher gold grades as compared with average background minerals is found in iron ore areas with a higher content of iron sulfides, pyrite and pyrrhotite. The discovered free gold in the form of thin plates is foil gold.

Determination of the grades not only for gold but also for all valuable elements contained in iron ores will enable assessing their extraction prospects in the form of by-products as early as at the stage of iron ore mining.

While conducting investigations into this matter, it is reasonable to study experience of Kazakhmys Corporation LLC.

Kazakhmys Corporation LLC is the largest copper producer in Kazakhstan that develops copper sandstones deposits of Zhezkazgan and Zhaman-Aybat (Cu, Pb, Zn, Ag, Re, Cd, S, Os), a gold-copper-porphyry deposit in Nurkazgan (Cu, Au, Ag, Mo, Se, S), pyrite-copper-lead-zinc deposits of Kusmuryn and Akbastau (Cu, Zn, Pb, Au, Ag, Cd, Se, S, Te), Shatyrkol porphyry-copper deposit (Cu, Mo, Au, Ag, Te, Se, U), Abyz gold-pyrite-copper-lead-zinc ore (Pb, Zn, Cu, Au, Ag, S, Se, Te, Cd, In, Hg), and Sayak group of copper-skarn deposits (Cu, Mo, Fe, Au, Ag, Bi, Te, Se, Re).

Deposits are developed using underground and open-cast mining methods at Zhezkazgan, Balkhash and Karaganda production sites. Copper grades in mined ores

* Corresponding author: adambekova_farid@mail.ru

have been decreasing steadily. Economic losses from the downward trend were offset by associated silver production.

Silver grades are low and therefore economic sustainability of mine production planning systems will heavily depend on possible online monitoring of copper and silver grades in exploration phase, in preparation and production mining as well as during ore delivery to processing plants. Based on the above, implementation of online monitoring of copper and silver grades would be addressing two independent objectives as follows:

- online monitoring of ores at the stage of exploration, mining and production;
- online monitoring of ores in transit to processing facilities. This study helps achieve this specific objective also addressing the issues associated with easing tensions arising between mining and ore processing facilities with regard to cyclone overflow metal redistribution.

This objective was being addressed within the framework of the Import Substitution Program administered by the Republic of Kazakhstan in the mining sector and as part of the range of projects aiming to retrofit and expand production at Kazakhmys Corporation LLC in 2017–2025.

Online monitoring of ores delivered to processing plants is highly challenging in technical terms due to the following factors:

- large ore size of ~300 mm;
- often heavily slimed ore;
- low silver grades (from 1 to 25 ppm);
- complex ores;
- ores come from different mining sources;
- at one of the facilities (Balkhash Processing Plant) ores are treated in a blend with Balkhash Copper Smelter slags characterized by highly complex grades matrix.

The above-listed factors clearly indicate that such a difficult objective has never been addressed successfully before regardless of the methods applied.

This study focused on ores brought to processing plants on conveyor belts as well as the material carried by underground conveyor belt at Nurkazgan Mine.

2 Method and geophysical apparatus

This study pursues the goal of establishing a unified, reliable and highly efficient online monitoring system of tracking the ever changing chemical composition of copper-bearing polymetallic ores at mining and processing operations of Kazakhmys Corporation LLC, which would focus on the key target element (copper) and equally on the accompanying (silver, cadmium, molybdenum) target elements.

To date, non-ferrous metallurgy has seen no examples of an efficient solution for online monitoring of ores with a particle size of ~300 mm and silver and cadmium grades of 1+ ppm by any physical methods on process conveyor belts using suspended ore controlling stations (OCS).

The global OCS market is diverse and offers

- energy dispersive X-ray fluorescence (EDXRF) systems such as OCS STARK (KrasnRados LLC, Krasnoyarsk), OCS-KM (Technoros LLC, Krasnoyarsk), Online

Conveyor XRF Analyzer Con X-03 (Baltic Scientific Instruments Ltd, Latvia), OCS ARP-1Ts (Tekhanalitpribor LLC, Moscow);

- Gamma Neutron Activation Assay (PGNAA) OCS such as CB Omni (Thermo Fisher Scientific, Australia), GEOSCAN (Scantech. Australia), NITA II (ScanMin Africa, South Africa), EBA 1-2 CE (ENCE GmbH, Switzerland); OCS based on NIR (near infrared) spectroscopy SpectraFlow Crossbelt (SpectraFlow Analytics Switzerland, Switzerland); OCS based on laser-induced breakdown spectroscopy (LIBS) MAYA-6060 (Laser Detect System - LDS, Israel) [1-5].

Only the EDXRF RCS can be best accommodated within the dimensions of the conveyor galleries at Kazakhmys Corporation LLC processing plants. Positive experience has been demonstrated using EDXRF OCS RLP-3-02 (Geotech LLC, Saint-Petersburg, Russia) at Zhezkazgan concentration plants (ZPP-1 and ZPP-2) since 2014 [6, 7]. During the production operation it was discovered that the OCS-RLP-02 was not capable of clear determination of low silver grades, which cast it out of the ranks of equipment to be included in the program.

The import substitution program dictated that EDXRF OCS RLP-21T (Aspap Geo LLC, Almaty, Kazakhstan) should be chosen as the base unit for the study. OCS RLP-21T was designed specifically to determine low (2+ ppm) silver grades (Fig. 1). The most advanced X-ray tubes, silicon drift detectors, the latest high-speed electronics and powerful software are used in the OCS, which ensured confident determination of silver and cadmium grades of 2+ ppm. This conclusion was made according to the results of bench tests on control powder and finely ground samples at ZPP-1 and ZPP-2.

Fig. 1. OCS RLP-21T.

At ZPP-1 and ZPP-2, ore is received from Zhezkazgan and Zhaman-Aibat deposits boasting higher silver grades compared to ores from other deposits (average grades of 15 ppm).

A much more complicated case is the Balkhash Processing Plant (BPP), which receives ores from Nurkazgan, Sayak Group, Kounrad, Shatyrkol, and Akzhal deposits and also treats waste slags from the Balkhash Copper Smelter (BCS) characterized by a highly complex elemental matrixes for interpretation by X-ray fluorescence method, e.g.: Cu=1.15%, Zn=5.90%, Pb=0.65%, Fe=46.80%. Ores treated at BPP have very low silver grades (usually less than 10 ppm, while Kounrad and Nurkazgan have less than 3 ppm) and a broad range of copper grades (0.2-4%).

Karagaily Processing Plant (KPP) treats ores from Akbastau and Abyz deposits. Nurkazgan processing Plant (NPP) only treats ore from Nurkazgan UG mine (NUGM).

A large number of OCS installation locations and several deposits within the scope of this study dictated the need to solve the problem in two stages. At the first stage of research, OCS-RLP-21T was tested on ore from deposits that are processed at ZPP-1 and ZPP-2. This stage helped identify the true scope of OCS RLP-21T capabilities in terms of sustainable performance on low silver and cadmium grades and recommendations were made on improving the hardware, methodology and software for the OCS RLP-21T to guarantee positive performance of the unit in the second stage (BPP, KPP, NIR).

3 Study results

After completion of the full cycle of bench and industrial tests of the OCS-RLP-21T on conveyors, in October 2016 it was launched on conveyor No. 1T ZhDM-2 (Fig. 2, left), and in January 2017 similar units were installed on conveyors No. 2T ZPP-2 (Fig. 3, right), and No. 1A ZPP-1 (Fig. 4, right) [6-7].

Fig. 2. OCS RLP-21T on conveyors No. 1T and No. 2T ZhDM-2.

The optimal measurement procedure was selected. Single measurements (1 sec) are performed one after another without gaps. grades of copper, zinc, lead and iron were calculated as averages of 20 single measurements; grades of silver, cadmium and molybdenum were the averages of every 40 single measurements.

Fig. 3. OCS RLP-21T on conveyors No. 1A (right) ZhDM-1.

In the course of control sample studies, the influence of the height of OCS suspension on copper and silver grade determination accuracy was evaluated. It was found (within an exposure of 300 sec) that when changing the height of the RCC suspension from 22 to 72 cm, the determined copper and silver grades did not change much:

copper was from 0.776 to 0.785%, and silver was from 10.95 to 9.8 ppm, but the measurement errors changed to a much greater extent: error for copper changed from ± 0.0088 to $\pm 0.038\%$, and error for silver changed from ± 3.2 to ± 18.0 ppm.

Fig. 4. OCS RLP-21T on conveyors No. 2 and No. 2A BPP.

Accounting for the variable ore-OCS gap in the RLP-21T OCS is carried out in two ways: by the MaxBotix MB7067 ultrasonic distance sensor; by the intensity of the scattered radiation of the elements composing the ore on the conveyor belt. MaxBotix MB7067 is the primary way to track the variable ore-PKC clearance. The results of the production operation of the two OCS RLP-21T units in 2019 at ZPP-1 are shown in table 1.

Table 1. The results of the OCS RLP-21T on the conveyor No. 1A ZPP-1 for 2019.

2019 month	Copper, %			Silver, ppm

The results of the production operation of the OCS RLP-21T in 2019 at ZPP-2 are shown in table 2.

The first stage of research on the introduction of the RLP-21T OCS was completed successfully and it was decided to move on to the second stage of tests.

All four new OCS RLP-21T units designed for more complex analytical tasks at the BPP and NIR in were equipped the following components: more powerful x-ray tubes with a working voltage of 60 kV; silicon drift detectors (SDD) of a larger area; state-of-the-art high-speed electronics; upgraded software package for new challenging analytical tasks. Two RLP-21T OCS units intended for testing at BPP had to be deprived of the unified calibration of the RLP-21T spectrometer and were switched to include on-object calibration. The desired calibration is selected automatically depending on the

grades of the main elements (as well as iron) and entries in weighing tickets. The remaining two OCS RLP-21T units retained the measurement procedure underpinned by the basic principle of Aspap Geo LLC: x-rayed objects are different in varying ore types with a range of ore processing products – delivered – all using the same calibration.

Table 2. The results of OCS RLP-21T on conveyors No. 1T and No. 2T at ZPP-2 in 2019.

2019 month	Copper, %			Silver, ppm

11	0,799	0,810	1,38	14,057	14,779	5,14
12	0,831	0,840	1,08	14,332	14,916	4,07
2019	0,820	0,812	1,03	12,577	13,044	3,71

Since zinc is contained in the conveyor belt components, the time intervals on an idle or moving empty belt (as per belt motion sensor readings) were excluded from the data sets.

Before installation on conveyors, all OCS RLP-21T units passed the standard set of bench tests. In this case, sets of calibration samples of ores from each deposit with known chemical compositions for all six elements were used. Each set included three types of samples: powders, roller-crushed ore, and jaw-crushed materials. After each OCS was suspended directly over the respective conveyors, the entire cycle of testing on the samples was repeated respecting the limitation of conveyor idle time availability for testing.

The results of the second stage of studies were as follows:

1. At the BPP OCS RLP-21T installed on the input belt conveyors No. 2 and No. 2A and commissioned on May 4, 2018 (Fig. 4). Detected elements were copper, lead, zinc, silver, cadmium, and iron.

Since July 2018, the railcar test station of the technical control department (TCD) on the KKD 1500/180 cone crusher was decommissioned [8-9].

The results of the production operation of the OCS RLP-21T in 2019 at BPP are shown in table 3.

Over the entire period of OCS operation the following silver grades were recorded in one railway train: maximum – 11.5 ppm (Tastau mine) and 12.3 ppm (waste slag); minimum – 1.9 ppm (Kounrad mine). This is much lower than the level of silver in ores entering ZPP – 1 and ZPP – 2. Thus, for the first time in global practice, EDXRF OCS was able to accurately detect such low silver grades in ores with a grain size of -300 mm.

2. At KPP the OCS RLP-21T unit was installed on conveyor belt No. 4 and commissioned on July 27, 2018

(Fig. 5). The ore size is -50 mm. Target elements are copper, lead, zinc, silver, cadmium, iron [8-9].

Table 3. The results of the OCS RLP-21T on conveyors No. 2 and No. 2A BPP in 2019.

2019 month	Copper, %			Silver, ppm		
	Overflow	OCS	σ , %	Overflow	OCS	σ , %
1	1,11	1,13	1,80	4,94	4,32	12,55
2	1,04	1,02	1,92	4,69	4,12	12,15
3	0,92	0,94	2,17	3,26	3,66	12,3

10	0,89	0,97	8,99	5,56	4,07	26,80
11	0,89	0,93	4,49	5,14	3,99	22,37
12	1,00	1,02	2,00	5,22	4,66	10,73
2019	0,949	0,993	4,65	4,889	4,137	15,39

Fig. 5. OCS RLP-21T on conveyor No. 4 KPP.

The following silver contents were recorded in one five-minute measurement: 19.6 ppm (maximum) and 6.5 ppm (minimum). This is another confirmation of efficiency shown by unique methodological and mathematical fragments of the OCS RLP-21T.

3. OCS RLP-21T unit on the main conveyor belt of the Nurkazgan underground mine was put into operation on June 14, 2018 (Fig. 6). Target elements are copper, lead, zinc, silver, cadmium, and iron.

Fig. 6. OCS RLP-21T on the main conveyor of the NPR.

The following silver and molybdenum grades were recorded in one five-minute interval: silver – 7.4 ppm (maximum) and 1.1 ppm (minimum); molybdenum – 0.1370% (maximum) and 0.0011% (minimum) [8-9].

4. In August 2019, the most recent modification of OCS-RLP-21T (the same as at BPP, KPP and NIR) was installed on conveyor No. 1 ZPP-1 (Fig. 2, left) to replace the OCS RLP-3-02 (Fig. 7). For ease of maintenance, this OCS folds the floor at an angle of 90° [9].

Fig. 7. OCS RLP-3-02 on conveyor No. 1 at ZPP-1.

The difference between conveyor No. 1 and conveyor No. 1A is that ore flow on conveyor No. 1 is noticeably more narrow than on conveyor No. 1A. Zinc is present in the material of the conveyor belt, so measures had to be taken to reduce the “viewing range” of the OCS RLP-21T. Sensitivity of the EDXRF method decreased and the decrease was compensated through applying 60 kV instead of 50 kV to the X-ray tube.

The results of production operation of the OCS RLP-21T in 2019 on conveyor No. 1 at ZPP-1 are shown in Table 4.

Table 4. The results of the OCS RLP-21T on the conveyor No. 1 ZhOF-1 for 2019.

2019 month	Copper, %			Silver, ppm		
	Overflow	OCS	σ, %	Overflow	OCS	σ, %
8	0,638	0,728	14,11	8,700	7,394	15,01
9	0,756	0,800	5,82	11,097	9,352	15,72
10	0,716	0,767	7,12	10,252	9,85	3,92
11	0,746	0,774	3,75	10,824	9,943	8,14
12	0,776	0,803	3,48	11,131	11,592	4,14
2019	0,726	0,774	6,61	10,401	9,626	7,45

The results of the RKS RLP-21T testing on conveyor No. 1 at ZPP-1 are not so successful compared to those from conveyors No. 1A at ZPP-1 or on conveyors No. 1T and No. 2T at ZPP-2. Based on 2019 performance, the calibration of the OCS RLP-21T will be slightly adjusted.

4 Conclusions

1. The unit for online grades monitoring of main (copper, lead, zinc) and related (silver, cadmium, molybdenum) elements in copper-containing polymetallic ores delivered to ZPP-1, ZPP-2, BPP, and KPP was developed, comprehensively tested and commissioned on production scale, and at ore mining facilities. The unit is based on

EDXRF OCS RLP-21T manufactured in Kazakhstan. The total of 8 OCS RLP-21T were commissioned.

2. For the first time in Kazakhstan’s non-ferrous industry a reliable online system for monitoring coarse -300 mm very low silver, cadmium (1+ ppm) and molybdenum (10+ ppm) grade ores was implemented on process conveyor belts on the scale of a very large mining company (Kazakhmys Corporation LLC). Real prerequisites have been established for the operational management of associated mining of these metals [14].

3. The problem was solved with minimal investments (a number of companies from Australia and South Africa had proposed to achieve this with the help of CSs using the gamma-neutron activation analysis method - PGNA; the cost of one such OCS exceeded the cost of the eight currently deployed EDXRF CSL RLP-21T units).

4. With the introduction of the OCS, the miners are provided with online information on the quantities of metals and metal grades of the ore delivered to the processing plant during the shift, day and month-to-date, and are now able to promptly make the necessary adjustments to the process of ore and metal mining. The reliable evidence base is available for them to stand their ground in terms of the qualities of ore delivered to the processing plant during redistribution of overflow metal treated through the processing plant in a calendar month.

5. As a result of OCS installation on process conveyors at ore processing plants, the standard quality control testing points on cone crushers were decommissioned: KKD 800/160 (ZPP-1), KKD 1500/1800 (ZPP-2), KKD 1500/180 (BPP) at ZPP-2.

6. Further practical application of the OCS RLP-21T is on conveyors carrying dried copper concentrate to Zhezkazgan Copper Smelter of Kazakhmys Smelting LLC (OCS CON-X from Baltic Scientific Instruments, Latvia is covering the scope at Balkhash Copper Smelter of Kazakhmys Smelting LLC).

7. OCS RLP-21T is used outside of Kazakhstan since 2019 when two OCS RLP-21T units were commissioned at CJSC Silver Magadan (Russia).

Ways of increase of efficiency of drilling-and-blasting

Borys Rymarchuk, and Oleksandr Shepel*

Kryvyi Rih National University, Department of Underground Mining of Mineral Deposit, 11 Vitalii Matusevych Str., Kryvyi Rih, 50027, Ukraine

Abstract. Results of theoretical researches and industrial experiments on technology of breaking of a massif with use of the artificial screens formed by lumbago of blasthole charges are resulted. In research the technology of breaking of ore by means of the vertical concentrated charges (VCC) on in advance formed screens is offered at underground mining. Possible ways of improvement of technology of working of deposits which will provide reduction of a production cost of ore are considered. The effective variant of a location of chisel developments, charges of the vertical concentrated charges (VCC) and artificial screens in the block is considered. It is analyzed the basic variants of formation of a shielding layer at breaking of ore by fans of deep boreholes and a location of boreholes in the coupled fan. The effective sequence of breaking of ore and necessary parameters of drilling-and-blasting is offered at underground mining. Comparison of results of measurements of granules of metric structure of the crushed mass on experimental sites of an ore mine is considered, analyzed and spent. The method of increase of efficiency of passage of the reflected and broken waves through the screen is offered at ore breaking. The considerable effect from explosion of charges in the presence of zones of unloading is resulted with is artificial they formed screens at massif destruction by the vertical concentrated charges.

1 Introduction

Raw-material base of ore mining branch of Ukraine are deposits of iron ores. Iron ore treating industry of Ukraine is in a condition of a competition to manufacturer's iron ore raw materials from other countries. For today Ukraine makes noncompetitive iron ore raw materials of underground mining in comparison with iron ore raw materials of other countries.

On a mass particle of iron it on 4–6 % more low, and behind a mass particle of earth silicon on 11–13% above, than in commodity iron ore which gets on the world market from Brazil, Australia, Sweden and other countries.

But the Ukrainian iron ore raw material holds out a competition at the expense of its lower price. Therefore the decrease of the cost price iron ore raw materials is the pivotal problem at mining of deposits.

The analysis of the mining literature shows, that scientific operations with effective solutions of the given problem at an underground extraction iron ore deposits is insufficiently at the present development of scientific and technical progress.

As practice of mining of ore deposits most the item of expenditure in mining shows ore deposit iron there is an ore breaking [1, 2]. It makes 25–30% from the general cost price on the block. Into this article enters: drilling of boreholes, blast holes, an explosive, means of undermining, a charging and undermining of boreholes and other. Cost price decrease under article ore breaking can give considerable economic benefit.

Considerable economy behind this article probably to reach if to lower expenses for drilling and an explosive. Explosive expenses should be connected with quantity of the bared surfaces in the block which is undermined. Usually at ore undermining in the block with one bared surface, or, for example, an interchamber pillar, a roof coal which two have, or even three bared surfaces one is used and too specific quantity of explosives on 1 t ores. It would be expedient to reduce expenses of explosives depending on quantity of the free bared surfaces in the block.

This dependence of specific expenses of an explosive at undermining from quantity of the bared surfaces is described by the known formula

$$q_n = q \cdot \sqrt{\frac{1}{n}}, \text{ kg/t}, \quad (1)$$

where q_n – quantity of an explosive at undermining of a massif with n the bared surfaces, kg/t; q – quantity of an explosive at undermining of a massif with one bared surface, kg/t; n – quantity of the bared surfaces, pieces.

If the bared surface faces broken-down rocks in this case fading of amplitude of waves of stresses there will be something smaller, than in a case with the bared surface of considerable width [3–6].

2 Methods

So, it is necessary to develop, or to improve existing technologies of working of deposits which are

* Corresponding author: fint_86@mail.ru

characterized by smaller indicators of specific expenses of explosives and ore production costs at application of effective breaking by means of the vertical concentrated charges [7–9].

3 Results and discussion

The general interest and scientifically-practical value is represented by a substantiation of breaking by charges VCC on is artificial they formed screens in the block which is undermined.

If instead of the customary bared surface (a surface of the compensatory chamber) there is a screen which represents intensively fissured from a lumbago of fans of boreholes a soil layer in this case the broken ground density will not be above 0,9 density of a massif. Reflexing of waves of stresses from such screen will be less, and absorption of energy of a falling wave considerable.

Breaking of rocks with use of shielding layers can be applied in conditions when the ore hardness and adjacent strata makes from above 10 on M. M. Protodyakonov's scale. With use of shielding layers in ores a fortress it is less than considerable researches of application of breaking of rocks 10 on M. M. Protodyakonov's scale were not spent, as in such ores and soils it is possible to use any other cheaper ways of breaking and types of explosives.

Let's consider what effect from explosion action will occur at it is artificial they formed screen from a lumbago of fans of boreholes in a block massif (fig. 1).

At simultaneous undermining of one or two fans of boreholes in a plane of their location opposite directed

distribution of cramping stresses from action of adjacent charges takes place. At their meeting in 3–4 times pressure raises, besides in a plane of a location of boreholes transformation of cramping stresses in stretching takes place that leads to cracking between charges. It sharply increases deficiency of a rock mass to the screen which will lead to change of its physical properties.

The most effective way of initiation of wells in a fan is counter initiation. At such way of initiation the best cracking in a zone between wells is provided, that considerably improves reflecting ability of shielding layers. In a fan, drilled on interchamber pillar boundary it is necessary to initiate wells a return method. It allows reducing in two and more times sizing of the maximum stresses on a free surface of a pillar and by that not to break its integrity. The shielding layer prevents distribution of waves of stresses deep into a massif. The wave of a stress formed from explosion of a charge, having reached boundary of a shielding layer partially (18 %) comes back in a broken massif that improves quality of crushing, partially (74 %) are absorbed by a layer of broken ground of a shielding layer and only 8 % of energy of a wave of a stress extend in an edge massif.

Except improvement of quality of crushing of the broken massif, shielding layer in 2–3 and more times reduce size of seismic fluctuations that allows to protect objects from destruction and to increase volume of simultaneously blasted out explosive without excess of admissible values of seismic fluctuations for protected objects.

Fig. 1. Variant of formation of a shielding layer: *a* – the scheme of drilling out of fans of deep boreholes $\varnothing 105$ mm; *b, b1* – the scheme of a location of boreholes in the coupled fan; *c, c1* – the form of a shielding layer after explosion of boreholes.

Presence of a shielding layer allows to destroy a massif aside opposite to a breaking direction (deep into a massif) on size of $0,7 \cdot W$ (burdens).

The fans of deep wells drilled for formation of shielding layers, are drilled out on sides of blasted out layers.

The side of a blasted out layer which is simultaneously a surface of funnels of release, is not drilled out by fans of deep wells. Before explosion VCC the turn of cone raises, except a cone raise located under VCC is made. The turn of these cone raises is carried out with slowing-down after explosion VCC. Formed from a turn of cone raises the bared surface is a shielding layer. If the blasted out layer at floor-chamber mining method or a block caving, collapses two VCC, located on a vertical first of all it is blasted out overlying VCC and from mile by second slowing-down undelaying VCC.

If power of a deposit is that, that the across the strike settles down two or blasted more out layer destruction of these layers is carried out in sequence from a trailing side to the lying. Before destruction of the subsequent blasted out layer release of the destroyed ore of the previous blasted out layer with a rocky pillow on the bottom is made.

Wave resistance of a massif and wave resistance of the screen differ in 2,5 times. Considering, that a stress at explosion of the concentrated charge (VCC) decrease in inverse proportion to a distance cube, and from a borehole column charge in inverse proportion to a distance square the distance from a charge to the screen will be equaled

$$W_{en} = \sqrt{\frac{m-1}{m+1}} \cdot W, W_{en} = 0,65 \cdot W, \text{ m}, \quad (2)$$

$$W_{es} = \sqrt[3]{\frac{m-1}{m+1}} \cdot W, W_{es} = 0,75 \cdot W, \text{ m}, \quad (3)$$

where W_{en} – distance from a column charge to the screen, m; W_{es} – distance from the concentrated charge to the screen, m; m – the relation of wave resistance of massif R_1 and screen R_2 ; ($m=R_1 / R_2$); W – a burden of breaking of a massif, m.

It means, that for reception of such stresses, as well as at reflexing from a free surface, the screen is necessary for forming on distance from a charge which is equaled 0,65–0,75W (Fig. 2).

Equality of time of passage of a wave of tension from the screen to a charge and run in the screen of a wave of compression and tension is a condition of the maximum refracting ability of the screen

$$\frac{W_e}{C_M} = \frac{2\Delta_{max}}{C_e}, \quad (4)$$

where C_m , C_e – speed of a sound in a massif and the screen in broken soils accordingly; m/s; Δ_{max} – the maximum width of the screen, m; W_e – a thickness of a layer of ore from a charge to the screen, m.

So,

$$\Delta_{max} = 0,5 \cdot \frac{c_e}{c_M} \cdot W_e. \quad (5)$$

This relation is customary $C_e / C_m = 0,65-0,75$, then
 $\Delta_{max} \approx (0,3-0,4)W_e$ or for a column charge
 $\Delta_{max} = (0,2-0,26)W$, for the concentrated charge
 $\Delta_{max} = (0,23-0,3)W$.

Fig. 2 Scheme of passage of the reflected and broken waves through the screen: *A* – a wave of compression from charge *Q*; *B* – a wave which is reflected from a wall I (a tension wave); *C* – a wave of compression which has driven through a wall I; *D* – the wave of compression which was reflected from a wall II, has turned to a wave of tension and has driven through a wall I in the side of charge *Q*; *E* – a wave of compression which has driven through walls I and II towards a massif.

Fig. 3. A location of charges VCC and artificial screens in the block: 1 – a layer which is undermined the first turn; 2 – layer which is undermined the second turn; 3 – VCC; 4 – the coupled fan of deep boreholes for formation of a shielding layer; 5 – boundary with pillar of the next chamber.

As energy of waves of stresses is proportional to amplitude square reflected energy of waves of stresses will be equaled

$$\frac{\sigma_{ref}}{\sigma_m} = \left(\frac{m-1}{m+1} \right)^2 = 0,18, \quad (6)$$

It means, that the screen from the rocks mentioned by explosion breaks a maximum of 18% of energy of a falling wave.

In this case, when on a way of waves of a stress the screen the formula 1 will look like is placed

$$q_n = q \cdot \sqrt{1/n_e} \cdot 1,22, \text{ kg/t.} \quad (7)$$

Formation of artificial screens is expedient for applying, if the massif is undermined by charges VCC and burden breakings reaches 20 and more meters. In this case having created the screen, probably, considerably to increase volume of soil which is broken and to reduce, thus, explosive expenses. The soil volume increases because the massif collapses, both towards the bared surface, and towards the screen.

Using technology of shielding of shock waves, probably to fulfill thick deposits of iron ores on the technology shown on (Fig. 3).

The essence of the above-stated technology of working of deposits of strong ores and magnetite

quartzite's consists in the following: 1) the basic massif of the block is broken by the vertical concentrated charges of explosive (VCC); 2) charges of the pseudo-spherical form (the relation of height of a charge to its diameter makes 5÷8) and is powerful 10–30 and more tons. Preliminary before explosion VCC shielding layers on all sides of the broken block (not having an exposure) are formed.

VCC settles down in a place of the explosive block which is the center of equally effective action of explosion. The stresses arising on a surface of the shielding layer and the bared surface of the compensatory chamber, from explosion VCC located in the center of equally effective action of explosion are equal.

The massif of the fulfilled block is divided by shielding layers into separate sites and each of them blasted out by one or two vertical concentrated charges of explosive (VCC), generated in vertical or horizontal workings. The shielding layer represents the destroyed layer of soil in the thickness $0,2 \cdot W$, located on the verge of the broken layer representing a parallelepiped in the sizes $40 \times 30 \times 30$ m (roughly).

On distance $0,7 \cdot W$ the filter behind all sides of the block which is broken except for the compensatory chamber and the block bottom is formed. In this case the volume of broken soil one charge VCC in the block will

increase almost twice, and expenses for breaking too will be reduced twice.

Breaking of rocks with use of shielding layers has been applied on opencasts of Buurdinsky and Hajdarkansky ore mines of Kirghizia in granite porphyrites by durability 10–12, chalkstones and jasperoid durability 10–14 on M. M. Protodyakonov's scale [10, 11]. The massif of soils was undermined by four numbers of boreholes. Last number of boreholes was undermined by the first, having created, thus, the screen from intensively fissured and partially broken grounds. Numbers of boreholes on soil loosening were then undermined. At these explosions the volume of broken ore has increased, and expenses of explosives for breaking have decreased for 20–25 % and the average size of a piece has decreased for 20%.

Change of all indicators on the average on 20–25% specifies in direct correlation dependence between increase of efficiency of the explosion, which directly proportional to quantity put aside the basic volume of destruction of energy of waves of a stress (25%) and size of an indicator of specific expenses of explosives. A penultimate number of boreholes have destroyed completely a layer towards the bared surface and towards a shielding layer.

Efficiency of application of shielding of waves of stresses at the expense of preliminary created screen [12] has been checked up on career of Inguletsky GOK.

In mining practice the way of separation of a broken massif is known for a method of preliminary formation of cracks. This method has a number of lacks. Formation of cracks is carried out by explosion of weak charges, in 6–7 times it is less, than a customary blasthole charge. The distance between wells in 3 times is less, than at breaking ground. However to create a crack at explosion of such charges not always it is possible, as there should be favorable conditions: the monolithic massif or a bedding of layers of ore coincides with a line of some the drilled wells. Besides, explosion of weak charges is not capable to form a crack. In a case if the crack nevertheless is formed, it will be insignificant width; therefore it cannot effectively shield a wave of stresses. The big share of energy leaves in a massif, therefore to

reduce expenses for drilling-and-blasting's it is not obviously possible.

For screen formation on boundary of the block which is undermined, last number of boreholes was charged by charges of explosives in volume on 30% less than customary charges of crushing. Last number of boreholes in the block was undermined in advance in relation to the second rows of boreholes (Fig. 4). At an instantaneous blasting of blasthole charges of such power the broken ground layer between the block and a massif is formed at any direction of beddings. Under such scheme of undermining the chopped ability of the screen which was formed, high enough. First row charges (at four numbers in the block) receive 12 % of energy of a reflected wave, the second row – 25 % of energy of a reflected wave, the third row – 50 % of energy of a reflected wave in addition to the basic energy of explosion.

Experiments have been spent in blocks: 30 – hor. 150 m; 804 – hor. 135 m; 95 – hor. 165 m; 93 – hor. 105 m; 105 – hor. 255 m. Blocks have been presented by soils durability 17–18 behind M. M. Protodyakonov's scale. In blocks it has been drilled on 4 numbers of boreholes. The distance between wells in a number did not change and made 6,5 m. Between numbers of boreholes distance has been increased by 1 m. Distance between boreholes of last number has been reduced by 0,5 m. Last number of wells has been blasted out in advance 100 msec.

Acoustic rigidity of a massif of the screen was approximately in 2,5 times less, than a massif. It modeled screening of waves of stresses for conditions of underground breaking. Undermining of charges carried out under the scheme presented on (Fig. 4).

For definition of quality of crushing of a massif measurements of granules of metric structure of the shattered mass on experimental sites of horizons have been executed 75 and 120 m. For comparison have been made measurements of granules of metric structure at ore undermining on customary technology in similar soils on horizons 95 m. Results of measurement (average values) are resulted in (table 1).

Fig. 4. The scheme of undermining of the block in advance boreholes of last number.

Table 1. Granules of metric structure of broken mined rock on research and control sites.

Site where were spent measurement	Fraction, mm					d _{ave}
	-100	100-200	200-300	300-400	>400	
Research sites (75 m, 120 m)	73,2	9,3	10,5	1,8	5,8	123
Control sites (95 m)	35,7	4,1	14,7	13,3	32,2	360

Improvement of quality of crushing of ore in the block testifies to increase in energy which is spent for the crushing, received for the account of reflexing of waves of stresses from a shielding layer.

Results of measurements of granules of metric structure show, that, despite a decrease of the expense of an explosive quality of crushing on experimental sites has considerably improved. Diameter of an average piece has decreased three times. Uniformity of crushing has essentially grown: the exit of fraction of a class - 100 mm has grown twice, and the exit of fraction of a class more than 400 mm has decreased in 6 times.

As a result of experiment it has been broken 552 thousand m³ ores, it is saved 157,9 t explosives. The general economic benefit in the prices of 2006 has made 264,7 thousand UAH. Including: from a decrease of expenses of explosives – 229,4 thousand UAH and from a decrease of volume of drillings – 35,3 thousand UAH.

4 Conclusions

According to Yu.P. Kaplenko researches [13, 14] the boundary of section of zones of unloading and the raised cramping stresses is the screen which breaks waves of stresses. Refracting ability of the screen that above, than is more difference in absolute sizes of stresses operating in specified zones. The customary massif which has no unloading zones, at explosion of blasthole charges caves in in the area of a location of boreholes. In the presence of unloading zones there is a shielding of waves of compression and their reflexing towards a charge to their transformation to waves of extension at the expense of what volume of broken soils increases by the same quantity of explosives in 1,6 times.

Such conclusions prove to be true supervision by results of massif breaking magnetite quartzite's on at Ordzhonikidze mine in the block + 8 axes charges VCC. In this block there were unloading zones therefore at explosion of charges on distance burden of 12–16 m breaking to the deep a massif made 5–6 m, and sometimes 10–12 m [15].

Considering such effect from explosion of a charge in the presence of an unloading zone it is expedient to form it is artificial screens especially at destruction of a massif by charges VCC.

Thus reduction of a production cost of ore can be reached at the expense of reduction of expenses of an explosive in the presence of the bared surfaces, or artificial formation of filters.

The study of the collapse zone by remote methods

*Oleksandr Dolgikh**, and *Liubov Dolgikh*

Kryvyi Rih National University, Department of Mine Surveying, 11 Vitalii Matusevych Str., Kryvyi Rih, 50027, Ukraine

Abstract. The aim of the research is to choose an effective remote method for surveying the area located above the space mined by underground mining. Often in separate sections of these territories funnels and dips are formed that do not allow the use of methods with finding the performer directly at these potentially dangerous sites. The research methodology is based on the implementation of survey work in the territory of the Ordzhonikidze mine, where underground mining is influencing the state of the ground surface and buildings. In this case, various remote survey methods were used. An analysis of the results of the survey work made it possible to determine the most effective method for studying dangerous areas in which horizontal and vertical deformations are observed. As a result of research, special attention was paid to the use of modern remote sensing methods for the territory of the mine. As a result of the analysis of the survey using remote methods, the expediency of applying the method of terrestrial stereo survey is determined, which has the necessary accuracy, and at the same time it is quite operational. The scientific novelty of the obtained results lies in the fact that the effectiveness of the use of ground-based digital stereo survey for studying the deformations of the ground surface and objects located in the mine and adjacent areas that are undermined by underground mining has been proved. The optimal conditions for performing stereo survey of the ground surface and objects of these territories are determined, and a scheme for performing the binding of survey stations is selected. The practical significance of the research is to study the deformations of the ground surface and buildings on the mine territory and adjacent areas, terrestrial digital stereo survey was used, which made it possible to quickly determine horizontal and vertical deformations for a large number of points with the necessary accuracy.

Introduction

The study of deformations of the ground surface and objects is an important task that many scientists and practitioners are involved in [1-5]. With the improvement of surveying and geodetic instruments and software for them, the level of research is being increased [6].

To increase the stability of underground mine workings, effective development systems are developed and implemented, which allows to increase the safety of mining operations and to ensure minimal impact on the ground surface and objects located on it [7,8].

The mine surveying service of the mining enterprise constantly monitors the deformations to which the ground surface and structures on it are exposed due to underworking by their mining operations. In coal deposits, surface deformations are characterized by insignificant values – millimeters, and in the development of ore deposits, their sizes can reach meters. It is known that such deformations often form zones of funnels, terraces, cracks, and smooth movement. The performed studies are devoted to issues of remote monitoring of the funnel zone and observations of the stability of the slopes of the formed

failures, using the example of the Ordzhonikidze mine, where in 2010 the collapse was accompanied by the formation of a funnel with an area of 17 hectares.

1 Analysis of remote deformation observation methods

Undoubtedly, the method that gives the most comprehensive information is aerosurveying, but it is not sufficiently informative in the study of vertical slopes [9-11]. Therefore, other remote methods can additionally be used:

- visual inspection;
- use of reflectorless total stations;
- laser scanning;
- scanning based on the use of interferometry;
- ground photogrammetric survey.

Visual inspection is an important priority measure, however, even the use of magnifying optics can only determine the fact of the most significant deformations in the form of cracks and landslides, but it does not make it possible to determine the metric characteristics of the processes. It is the detection of cracks during visual inspection that justifies the implementation of further instrumental studies. Today, from a distance of 650-700 meters visually determine the nature, size and dynamics

* Corresponding author: dlavgeod@gmail.com

of deformations, even approximately, it seems impossible.

Reflectorless total station is the simplest method that does not require special training and can be performed by an ordinary mine surveyor of a mining enterprise. 10 years ago, electronic total stations with a reflectorless mode up to 1000 m were very expensive and therefore rare. But by the time of the collapse of 2010, the surveying service of the Central GOK had a similar Topcon GPT-3000 device for operation. The first studies of the danger zone in the Ordzhonikidze mine started almost immediately after the collapse, and were performed by this total station by specialists of the mine surveying department of the plant, together with the researchers of the mine surveying department of Kryvyi Rih National University. The use of electronic total stations at the mining enterprises of Krivbass has its own specifics. Dark rocks absorb the rays strongly, and the total station, with a passport value of the reflectorless mode of 1000 meters, actually measures the distance up to 600-650 meters. Naturally, this is not about the characteristics of the device or its malfunction, but about the influence of rocks on the measuring process. This total station without any problems measures the distance to bright objects, for example, to a white wall or a light strip on a chimney at a distance of 980 meters, although it consumes a huge amount of energy, which significantly reduces the battery life. The decrease in the range of the reflectorless mode introduced its own corrections into the observation program, namely, it contributed to an increase in the number of points of polygonometric moves, from the points of which the survey was directly performed. The binding of polygon moves was carried out to the points of the state geodetic network of this region, which are outside the zone of influence of mining operations.

Using the reflectorless mode of the total station, for several days of work the coordinates of 332 points were determined, the total number of which includes not only reference points, but also points of polygonometric moves (Fig. 1, 2).

Fig. 1. The scheme of binding moves.

Fig. 2. The scheme of surveying using a reflectorless total station.

As a result of studies, it was confirmed that the use of the method of reflectorless total station in the quarry has significant disadvantages: the presence of a large number of dead zones; the inability to do surveying work in some areas because of the danger of being on them or because of the presence of dense vegetation.

Also a remote method is laser scanning. Laser scanners at the time of the release of the crow in 2010 had a high cost and, at the same time, parameters that did not allow such observations to be performed. It is worth noting that the above disadvantage of reflectorless total station - signal absorption by dark rocks, is equally true for laser scanners. Therefore, for such a survey, you need to have a scanner with a range of at least 1500 meters. Such devices are rare and quite expensive today. In addition, the use of scanners impedes the availability of vegetation. For these reasons, laser sanitization was not used to study the collapse zone and adjacent territories.

It is known that scanning based on the use of interferometry is also a remote surveying method [12]. This method has high accuracy (up to 0.1 mm) in the study of open pits and dumps by comparing two surveys for different dates, but is not applicable for this survey. This technology is very promising and will certainly find application in the mining enterprises of Krivbass, but at the moment its application is complicated by the high cost of equipment and the need for constant protection.

The next of the methods under consideration, which has become the main one along with reflectorless total station, is the method of terrestrial stereotopographic survey. It is worth noting that for this area much later aerial surveys were performed, the results of which almost coincided with the ground. Based on its results, sections were added for which it was impossible to shoot using other methods.

Stereotopographic survey over the past ten years has become completely different. The development of terrestrial stereotopographic surveys in Kryvyi Rih quarries has had its ups and downs. This method is very popular in the seventies of the twentieth century, was practically no longer used in the mid-eighties and early nineties. There were many objective and subjective reasons for this, one of which was the physical and moral obsolescence of filming cameras and

photogrammetric instruments for processing images. An important reason is the transition period in the development of Ukraine, which was characterized by the collapse of all economic relations and the decline of industry.

Stereotopographic survey in Ukraine acquired a new life with the advent and development of the digital photogrammetric station “Delta” and the software product Digitals, produced by GNPP “Analytics” and LLC “Geosystem”. It should be remembered that in the Russian Federation at least three digital photogrammetric stations, such as Photomod, Talka and military developments, were also developed. But they were not widespread through an inflexible pricing policy or focus on the military-industrial complex. Therefore, with the acquisition in 2003 of the DFS “Delta” digital camera and in 2005 the EOS 350D digital SLR camera began a new but already digital ground-based stereotopographic survey. In the second decade of the 21st century, there was another improvement related to the emergence of such software products as Pix4d, Photoscan, etc.

2 Research of simultaneous surveying

The need to have certain initial data for orienting the images and the fundamental difference in the obtained

results of their processing often complicate the modern digital processing of images of old surveying. The difference is observed in many ways: in the ways of performing the necessary snapping to the image; in the number of survey stations, for example, before there were enough using two stations but now, by using of modern methods, they need more than three; in the need for GPS-snapping to the images. You can manually enter GPS tags in the EXIF data of images, but it will take a lot of time, for example, for 250 images to enter GPS coordinates. Therefore, the combination of new and old surveying in plan is very painstaking work. But the determination of the necessary data on the position of multiple points of terrain or object at one physical moment and the possibility of using them after a considerable period of time is one of the main advantages of photogrammetry.

The pictures were taken for the research of the collapse zone for the surveying dates of August 27, 2010 and July 31, 2019. The survey for August 27, 2010 consisted of 142 eight-megapixel images, of which 11 stereopairs were formed, and the rest of the images were used for the photo documentation of the terrain. The coverage area by stereo pairs is shown in Figure 3.

Fig. 3. The terrain coverage with stereopairs surveying for the date of August 27, 2010.

As can be seen from the above scheme of covering the terrain with stereopairs, with an object area of 380,722 m², 196,412 m² was covered with stereopairs, which is almost 52% of the total area. The accuracy of the planned position of the points due to errors in the external orientation of the stereopairs ranged from 0.01 m to 0.20 m, which meets the requirements of the instructions for performing surveys performed for quarries, that is for the researched object.

Archival pictures of 2010 at that time met the requirements of stereotographic surveys, but preparing them for Pix4D or Agisoft Metashape software products took considerable time. When preparing the 2010 survey data for processing according to the program, most of the time was required to determine the coefficients needed to convert the coordinates from the conventional mine coordinate system to the given one. This is necessary to bring the coordinates of the points of the survey justification to a single coordinate system. For this purpose, three points were coordinated at the industrial site using the Topcon GPS receiver in the static mode and the coordinates of the points Ct1, Ct2, Ar1 and D1 were determined using the polar method from two points 92 and RPC0. Coordinates 91, 92 and K1 are determined with an accuracy of 3mm in plan and 5mm in height. Measurements at steps 92 and RPC0 were performed with a Sokkia SET630R total station in reflectorless mode. The errors in determining the coordinates of the points Ct1, Ct2, Ar1 and D1 ranged from 15 mm to 30mm in the planned position and up to 30 mm in height. The choice of points Ct1, Ct2, Ar1, D1 was not accidental – these are practically the only contours that have remained unchanged for nine years and were recognized with high accuracy in the images for the start and end dates of the surveys (Fig. 4). The presence of green spaces greatly complicated the search for points that would be accurately recognized in the images for both dates.

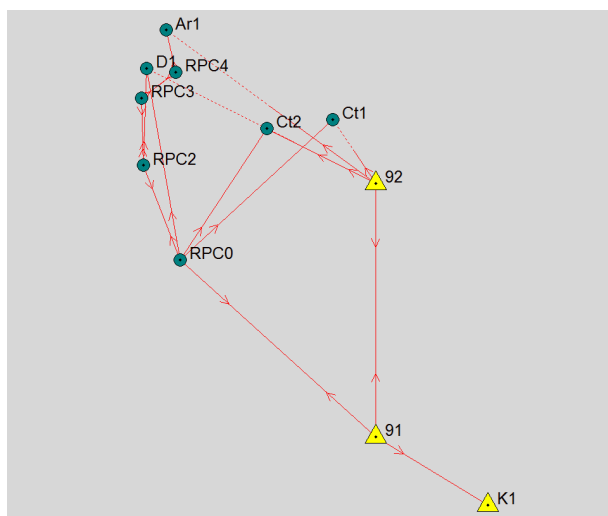

Fig. 4. The scheme of the points of reference and surveying justification.

As a result of processing the pictures taken in 2019 using the Pix4d program, the following errors in the position of the control points were obtained: along the X

axis, not more than 139mm; along the Y axis – 138 mm; along Z – no more than 33 mm (Table 1).

Table 1. The accuracy of determining the coordinates of control points according to the survey in 2019.

The points of the surveying object were referenced using GPS Receiver GP-E2 in the WGS 84 coordinate system (EGM 96 Geoid), and the identities were referenced in the Pulkovo 1942 / Gauss-Kruger zone 6 coordinate system (EGM 96 Geoid) by three-point direct intersection.

3 Determination of deformations from the results of processing surveys for different dates

To reduce the errors in determining the position of the points, the 2010 survey was divided into two parts – left and right, which were processed separately. Figure 5 shows a digital model in the form of a point cloud based on the results of the survey in 2019, and Figure 6 presents a digital model in the form of a point cloud according to the results of the 2010 survey.

The diagrams were constructed according to the results of processing the survey data characterizing the magnitude of the deformation of the pit side along three

(X, Y, Z) or two (X, Y) axes (Fig. 7). The blue color shows the areas with minor changes – from 0.01 m to 0.10 m, and shades of green show the areas with strains from 4m to 6m (the shade of green depends on the amount of deformation). The yellow and red colors show a deformation of more than 8 meters.

Figure 8 shows in different colors the strains obtained at the 2010 survey date. Analysis of the color change led to the conclusion that the deformation is concentrated in four zone.

Fig. 5. The digital model created by the results of surveying in 2019.

Fig. 6. The digital model created by the results of surveying in 2010.

Fig. 7. The deformation of points on the side of the quarry according to the survey in 2019.

Fig. 8. Zones of maximum deformations.

Fig. 9. Sites of the studied second (a) and third (b) zones.

The first zone characterizes the sliding of the side with the formation of the approach. From the mine site, on the profile line adjacent to this zone, strains of up to 1000 mm in plan and 1500 mm in height were observed. Such deformations in magnitude led to significant changes in the surface, and for safety reasons the territory was fenced. Therefore, further observations are carried out only by remote methods.

The second zone combines three areas of rock mass scree with dimensions of about 15 m x 10 m x 5 m, which occurred due to the flattening of an almost vertical side. The analysis showed that the deformation is facilitated by the geological structure of the site, as shown in the image of this site (Fig. 9a). The site is composed of bulk rather than rock formations.

The third zone is the site with the most large-scale changes. In this area, the promotion of the crow zone is the most significant and has affected buildings and structures. The site is composed of rocks. No cracks were observed on the site in 2010 (Fig. 9b), and in 2019 a large number of them appeared, which indicates active processes and array stress. Therefore, it was this area that was investigated in more detail. From the industrial site, profile lines were laid on this site to monitor the condition of the mountain massif and predict possible collapses.

The fourth zone is the epicenter of the funnel, so increasing it by 5 meters inland is logical. But only the upper layer underwent a change to a depth of 5-8 meters, bedrock is characterized by sufficient stability and a constant position for 9 years of observation.

The most efficient and accurate method for such studies can be considered laser scanning. To perform research on this object, a laser scanner with a range of 1

km is required. The performed studies have led to the conclusion that it is advisable to use ground-based digital photogrammetry for this method, which can replace laser scanning, and will also make it possible to assess the reliability of the results. Two surveys were performed in 2019 for this with an interval of seven days. A short interval between surveying made it possible to use the same points as signs. It was found that under almost identical surveying conditions, the errors of the initial data can be neglected. With sufficient accuracy (3-5 cm), a uniformly blue surface of changes is observed.

Surveying for the date of August 21, 2019 was performed from 11 survey stations that were selected with the fulfillment of the security conditions for the work of the performer (Fig. 10). The selected observation conditions did not allow us to arrange the bases of surveying perpendicular to the object. Therefore, the pictures were taken with a significant bevel to the right (more than 600), which negatively affected the accuracy of the results.

Fig. 10. The scheme of the surveying bases location.

Fig. 11. The position of points with different errors in determining spatial coordinates.

Fig. 12. The distributions of errors in determining the position of points.

The above figure characterizes the accuracy of determining the position of points based on the results of ground-based stereo surveys in the study of slope deformations. In the figure, the blue color corresponds to the studied points, which have a complete coincidence of the spatial position for two dates with an accuracy of 0 mm to 10 mm, which is 37.4% of the total number of points. The number of points whose spatial position coincides over two dates with an accuracy of 10 to 25 mm is 27.0%. The graph (Fig. 12) shows data on the number of points in percent, the accuracy of determining the positions of which correspond to different values.

As can be seen in the graph, 89% of all points have errors in determining the position of points up to 50 mm and 11% – from 50 mm to 75 mm. Most of the points with errors from 50 mm to 75 mm correspond to areas with vegetation; therefore, when cleaning a cloud of points using a filter, their number decreased by three times and corresponds to 3%.

Conclusion

When studying the deformations of the ground surface in the collapse zone from the Ordzhonikidze mine, a digital survey was used, which made it possible, using a 24-megapixel camera with distances of 600-700 meters from the object of study, to obtain the accuracy of determining the spatial coordinates of cloud points from 0 mm to 50 mm. The resulting accuracy is lower than the accuracy of laser scanning, but has advantages when shooting from large distances to the subject. Further research is aimed at improving the methodology for performing survey work and photogrammetric image processing, which will improve the accuracy of determining the spatial coordinates of the studied points and the effectiveness of digital shooting.

The tragic consequences of the collapse of the earth's surface within the mining allotment of Ordzhonikidze mine

*Oleksandr Ye. Lapshyn, Oleksandr O. Lapshyn, and Mykola Khudyk**

Kryvyi Rih National University, Labor protection and civil safety Department, Kryvyi Rih, 50027, Ukraine

Abstract. The purpose of this study is to draw the attention of scientists and mining workers to the importance of working off mineral deposits within the permissible parameters of mining and technical production, the failure of which leads to tragic consequences. Based on the analysis of physical data of the rock massif and the geomechanical condition of the exhausted space within the mine field, the causes of disturbances of the stability of the inter-dimensional pillar, its deformation and displacement were determined. The negative and dangerous factors of underground mining are given, which lead to the formation of large cavities, which are kept from collapses due to the inter-dimensional pillar and the thickness of the rocks that supported it. An analysis of the field development violations is given regarding the application of inappropriate systems of development, legislation, regulations, and inefficient design decisions that led to the accident that resulted from these violations. The actual consequences of the accident, which resulted in extensive destruction of the earth's surface, human casualties, seizure of cars, communications, buildings, roads, etc., are presented. Recommendations are given to prevent the collapse of the earth's surface, the destruction of buildings, and the death of people.

1 Analysis of research and publications

A great deal of research has been devoted to the study of the causes and consequences of violations of the technology of underground mining of iron ore deposits, which lead to uncontrolled destruction of safety pillars and the collapse of the earth's surface. Some of these studies explain the uncontrolled destruction of safety pillars due to the lack of proper monitoring of the state of the mountain, disturbed by mining operations, the definition of criteria for forecasting emergencies and the limits of the impact of mining operations on the stability of the earth's surface [1-4]. The authors of these studies believe that monitoring the state of the earth's surface in mining operations will prevent collapses and also avoid distortions of gas and water pipelines.

In the works related to the improvement of the concepts of systematic management of mining processes, it is emphasized that further studies should be directed to the development and improvement of existing technologies of underground mining of iron ores by systems of development with the bookmark of the produced space, which will avoid uncontrolled collapses [5-7].

From the side of the researchers, who pay attention to the necessity of developing a state program of a complex solution of the problems of the Kryvyi Rih iron ore basin (sinkholes and landslides, technogenic earthquakes, etc.). It is concluded that this is possible only at the state level with the attraction of considerable funds, specialized institutions, joint activities of mining specialists [8].

Analyzing the economic and environmental aspects of the technogenic region of Kryvbas, the study shows that the practice and accumulated experience of mining enterprises show that the costs of implementing measures to prevent possible emergencies related to the disturbance of the daily surface in the form of cracks, subsidences and sinkholes are significantly lower than losses to eliminate them [9].

2 Setting objectives

Underground mining is associated with the formation of voids, the untimely repayment of which or not laying them can lead to the uncontrolled collapse of safety pillars and the destruction of not only underground structures but also buildings on the surface of the mine. The purpose of this study is to identify the causes of the collapse of the earth's surface of the mine and to develop recommendations for preventing the uncontrolled destruction of barrier safety pillars within the mine field, which is set aside for the development of mineral deposits.

3 Results and discussion

The subsidence of the earth's surface occurred on June 13, 2010, within the mine drainage of mine Ordzhonikidze PJSC "CENTRAL GOK". An array of rocks, where the uncontrolled displacement of the earth's surface occurred, composed of deposits of ferrous

* Corresponding author: khudyk.mykola@gmail.com

quartzites 18-20 m thick, has dismemberment with geological disturbances. Under the oxidation zone, which extends to a depth of 280-380 m, magnetite quartzite was extracted by treatment chambers in the southern and northern wings of the mine. As a result of the ore extraction, waste spaces were formed in both wings from 120 to 200 m. These waste spaces were entirely separated, partially filled with rock, which supported the pillar at its bottom. The array of undermined rocks rested on the rear, which was the mainstay of the north and south wings of the minefield.

The geomechanical condition of the undermined rock massif was such that equilibrium could be formed, since it became a lever whose place of pinching was the unbroken indigenous rocks, and the point of displacement was a pillar. This load concentrated the load from the undermined array of both wings, as from a lever. Besides, the undermined array could be displaced by layering, since within the minefield, it was dismembered by geological shifts, which contributed to its weakening. The weakened fossil mass was further exacerbated by the existing collapse zones created by the mining of rich ores.

The state of the pillar is evidenced by three of its dumping, which occurred in 1988 (two years after its formation), with the thickness of the pillar of the project being 30 m, and in places of dumping remains up to 15 m. Further dimensions are not available due to the difficult approach to measurements, but the state has increased due to the direct mining of ore in the chamber from 2006 and next to it in 2007-2008 with a floor of 527 m.

Thus, the undermined array of rocks of the northern and southern section rested on the pillar, and through the pillar was transmitted to the ceiling of these chambers and, consequently, to the inter-dimensional pillar floors of 527 m.

The pillar horizon of -170 m was composed of oxidized quartzites, which are 2-3 times less than magnetite ones. It follows that the tense state of the pillar was such that any slight effect on it could lead to its destruction, and as a consequence – the destruction of the support that supported the massif, and this could contribute to the collapse of the worked out mountain range of the northern and southern section.

Slowly, for many years, the increase in the mass of the overlying rock and the plane of its outcrop caused the approaching of the limit state without showing signs of destruction. The massive explosion that took place triggered the displacement of the rock mass, resulting in a cone of influence, with the following parameters: area 165 thousand m²; collapse on the lying side of the deposit up to 80-82 m; on the hanging side – 5-20 m; void volume – 7.0 million m³; the volume of waste space along the southern and northern sections is 7.2 million m³; used space fill factor – 0.97.

The mining circumstances in which the accident occurred are as follows. The raw material base of Ordzhonikidze mine is a deposit of magnetite (ferruginous) quartzites "South-Magnetite". This deposit is revealed by the main air-shaft of the Ordzhonikidze mine and the ventilation shaft of the mine "Chervona".

Development system – floor-chamber. The testing of inter-chamber pillars (ICP) was carried out by a surface collapse. During the mining of the magnetite quartzite deposit, the mine was guided by the design and technical documentation developed by the State Enterprise "State Institute for Design of mining enterprises "Kryvbasproekt" and the technical department of the Ordzhonikidze mine. Together with the design documents, which were studied by the State Commission for the Investigation of the Accident, scientific reports of the Scientific-research mining institute of the Kryvyi Rih National University (NIGRI KNU) on the carrying out of research work in the period from 2000 to 2009 were presented.

According to the expert commission, appointed by the decision of the special commission to investigate this accident, the design documentation was sufficient for the safe development of the field and the control of the rocks. However, during the mining process, deviations from the project timetable for stock extraction were allowed. So, ICP in the surveyor axes (-4) and (-11) was refined later by 8-12 years, and ICP (-3) axes were not refined. There were also deviations from the "The project of preparation and development of the deposit "South-Magnetite" in axes (-45) - (+40) floors 447-327 m", 1987 and from the "Project No. 37 on preparation and testing of magnetite quartzites in block (-7) and ICP (-11) and (-3) axis of floor 447-304 m", 1987.

In order to produce magnetite quartzites, a mass explosion was carried out at the Ordzhonikidze mine on June 13, 2010. The total mass of the explosive used was 65042.5 kg. The mass explosion was carried out by blasting deep wells, as well as by lifting workstations, which housed concentrated vertical charges. The mass explosion was monitored by NIGRI KNU staff, according to a scientific agreement on the topic "Monitoring of values of seismic oscillations of the soil and shock-air waves on the condition of the construction structures of buildings and structures located in the area of blasting on the quarries and mine Ordzhonikidze".

On the day of the mass explosion, four employees of the blast management laboratory and the seismic mine were delivered to the Ordzhonikidze mine by GAZ 22-17 car ("Sobol"), driven by driver V. S. Vavruk. The seismic equipment locations were determined in advance outside the minefield. After placing the observation posts, the driver V. S. Vavruk, without entering the territory of the industrial site, put the car near the construction of the mechanical workshops of the mine, in which he intended to wait for the completion of the surveillance work.

Immediately after, the explosion began an intense collapse of the daily surface, which was in the mine drainage area. At the distance of 20 m from the checkpoint No. 9 (CP-9) in the southwest direction there was a subsidence of the earth's surface, together with an array of pressure rocks over a clearing space of about 360 m in length, and in the perpendicular direction – 450 m, with a plane approximately 16 hectares. The subsidence of the earth's surface (displacement) on the side of the lying side of the reservoir was a maximum of

82 m and 20 m minimum, and on the side of the hanging side of the formation bed, it varied from 5 to 20 m.

Due to the subsidence of the earth's surface, a part of the highway 20 m from the CP-9 went into the abyss together with three private cars and GAZ 33-023 "Gazel" cars owned by PJSC "CENTRAL GOK" and GAZ 22-17 "Sobol" owned by NIGRI KNU, which stood before the CP-9. Driver V. S. Vavruk, who was at the time of the incident in the cockpit of the car "Sobol", received injuries that are not compatible with life.

As a result of subsidence of the earth's surface, the following destruction occurred in the mine drainage zone of Ordzhonikidze mine (Kryvyi Rih):

- damaged the 6 kV transmission line, which was one of the inputs of electricity supply to the mine;
- damaged gas pipeline, which provided gas to residents of settlements located outside the mine drainage area of Ordzhonikidze mine;
- destroyed construction of mechanical workshops of the mine;
- destroyed mine headgear of the ventilation shaft "Chervona";
- destroyed the ventilation shaft "Chervona" intended for ventilation of the mine workings of the Ordzhonikidze mine;
- the substation "Chervona" from which part of the residential sector was fed;
- requested the Brotherly Tomb of the soldiers killed during the liberation of Kryvyi Rih;
- destroyed the public highway leading from CP-9 along Brotherly Tomb to residential areas;
- destroyed the former construction of a repair shop;
- cracks of the earth's surface and the asphalt part of the site were formed on the territory of the Ordzhonikidze mine;
- three private cars, a car for cargo and passenger transportation, GAZ 33-023 "Gazelle" owned by PJSC "CENTRAL GOK" and a car GAZ 22-17 "Sobol" belonging to NIGRI KNU failed.

The State Commission of Inquiry into the accident at the Ordzhonikidze mine established technical and organizational causes and recommended such basic measures to eliminate the causes of the uncontrolled collapse of the earth's surface when developing the deposit "South-Magnetite".

Technical causes:

- unreasonable choice of systems and technologies for the development of oxidized magnetite quartzites, which by physical and mechanical properties are capable of forming the process of self-destruction;
- failure to comply with paragraph 1.2.2. Regulation on designing of mining enterprises of Ukraine and determination of mineral resources of 07.05.2004 No. 221.

Organizational causes:

- not an effective designer's service by NIGRI KNU, as it was only observational. At the same time, reports were issued that did not provide specific suggestions for creating preconditions for self-deception and did not provide an analysis of the effectiveness of the technology used;

- retreats from the "Working project of mining works and collapse of overlying rocks during mining of magnetite quartzite deposits above the horizon of 447 m of the Ordzhonikidze mine". Violation of the schedule of completion of the field, which did not contribute to the normal development of the process of self-destruction;
- the necessary measures were not taken, and the driver has not indicated a safe parking place at the time of the mass explosion.

Measures to protect the surfaces of mines from collapse should include:

- safety of people in buildings and sites located in the designated area;
- the preservation of objects for the purpose of their operation for the whole period of existence of the mine;
- preventing the ingress of water and flooding of mines when undermined water objects;
- prevention of excess losses of minerals or their conservation;
- prevention of unjustified premature demolition or transfer of structures;
- the possibility of applying, where necessary, joint development of deposits in open and underground ways.

The main measures for the protection of objects from destruction during the underground development should be considered as follows:

1. Mining measures that reduce the deformation of rocks and the earth's surface: application of special systems of development, laying of the produced space, incomplete excavation of minerals, the introduction of the special order, and sequence of working out of reserves under-protected objects, etc.

2. Structural measures that allow to maintain permanently or extend the life of structures at deformations of the base exceeding the limit values: separation of buildings into sections using deformation seams, reinforcement of load-bearing structures employing steel rods, stretch marks and reinforced concrete belts, installation of various types and components artificial reinforcement of the foundation of the structure by creating retaining walls, cutting slits, etc.

3. Carrying out of repair and restoration works: repair of a roll and lifting of the densest parts of buildings and constructions through jacking, filling and straightening of joints of rails repair of a roll of support of transmission lines, bypass of power lines, regulation of crane ways and other work to bring the facility to a state that meets the requirements of maintenance.

4. Temporarily change the nature of the operation of the underworked object.

5. Moving structures on not underworked areas.

6. Special monitoring of the development of the displacement and the condition of the underworked objects in order to detect dangerous deformations promptly and take appropriate security measures.

7. Provision of a safety pillar for an object if other protection measures do not ensure its normal operation or are economically impractical.

The protection measures for existing sites are determined by a mining company that develops mineral resources or, on its request, by a special organization and approved in due course. Safeguards for the projected

construction site, as well as the projected deep horizons, are selected by the design organization. When approaching the area of impact of the underground development to the protected object, the planned measures should be revised and corrected in order to prevent the occurrence of emergencies. Any construction of sites in mining impact areas must be agreed with the governmental organization responsible for the proper and safe use of minerals.

Before the drafting of the project of protection of objects located in the areas of influence of underground mining, it is envisaged that they are thoroughly inspected by a commission organized by the mining enterprise. The commission should include representatives of the company, owners of the objects to be guarded, and representatives of the organization that should design the security measures. The survey results are drawn up with an act detailing the technical condition of the object.

In the case of large-scale blasting operations, such as a mass explosion, the commission shall repeat the inspection of the blast zone and amend the security measures to determine the necessary costs of restoring the safe condition of buildings, structures, pipelines, and electrical networks and equipment. Draft measures for

the protection of objects located in the area of influence of underground mining works are approved and approved following the procedure established by law and by the rules for mining operations [12]. State mining authorities control responsibility for the timely and correct selection of security measures and their implementation. Business protests against disagreement for damage, such as the destruction of structures and communications, are resolved under the law through the courts. According to the court, the mining company, which was responsible for the rockslide or collapse of the surface and the destruction of structures and engineering communications, must at its own expense, restore communications, repair, or restore the destroyed objects.

After revealing by the state commission, the nature of the process of rock displacement, the destruction of the surface, its contours, and the depths of the dips are applied to surveying cuts and plans. The scheme of the zone of deformation of the rock massif and the earth's surface is shown in Fig. 1, where shear zones, cracks, terraces, funnels, and dips are traced. This scheme was proposed in 1975 by the Institute of Mining Mechanics and Surveying (IMMS).

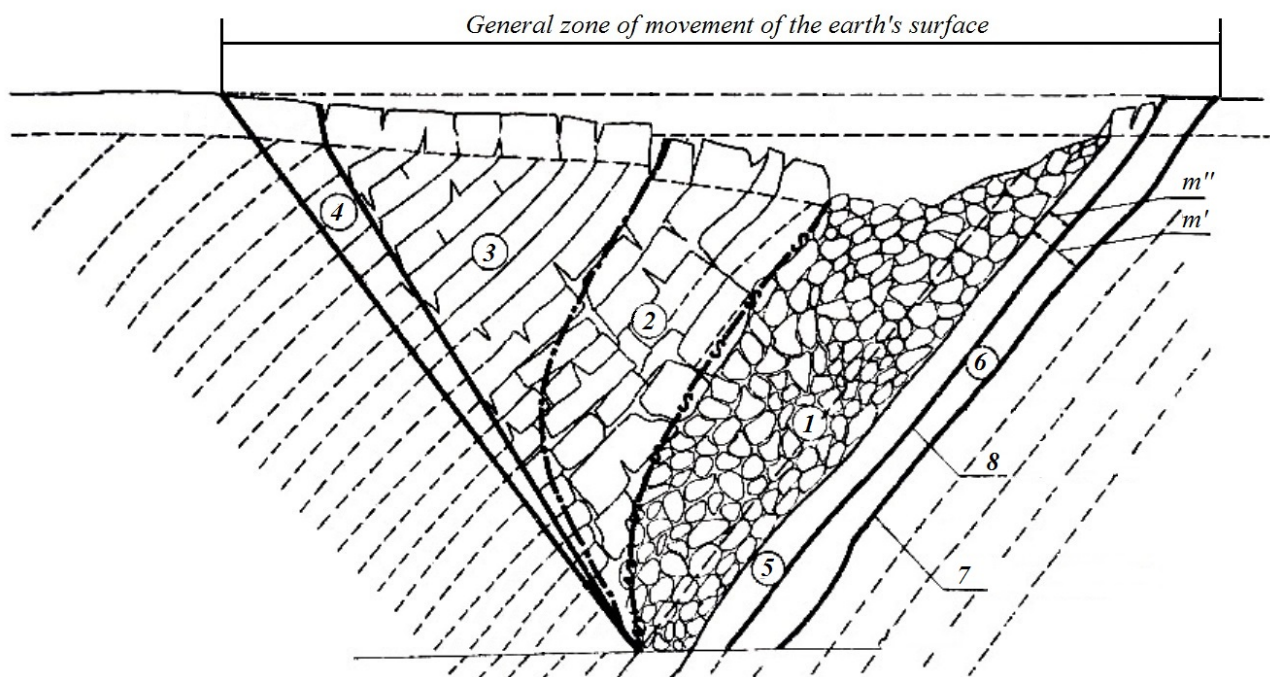

Fig. 1. The scheme of zones of deformation of the rock massif in the hanging and lying sides of the deposit according to IMMS: 1 – cone of influence; 2 – subduction zone; 3 – fissures zone; 4, 6 – smooth shift zone; 5 – fissures zone and subduction zone; 7 – displacement line; 8 – line of shear; m' – thickness of layer smooth shift zone; m'' – thickness of layer fissures zone and subduction.

According to the conclusion IMMS, the zone of landslide displacement is the area that is affected by underground mining if the deformations of the rock mass exceed the permissible values. In this case, in the hanging side of the deposit, shear zones are formed, which are characterized by certain physical and mechanical features:

1. The zone of cracks in which deformations are accompanied by the bending of hinged rock slabs with the formation of cracks, the loosening ratio is less than

1.1. Coming to the surface under sediment, this zone causes them to bend and stretch to form a zone of cracks on the surface of the earth.

2. The area of smooth bending is characterized by the fact that the layers of rocks bend with the formation of unconnected small cracks, the loosening ratio in this zone is close to 1.0. Depending on the deposits, this zone causes the transverse deformation of the layers and slope without breaking the continuity with the formation of a zone of smooth shifts of the earth's surface.

3. The shifting zone of rocks along with the layer in the lying side of the deposit, in which the contact thickness of the rocks is stratified into individual packs, is displaced by the layer. Depending on the deposits, this zone causes them to shift with the formation of cracks and terraces on the earth's surface.

4. The zone of a smooth shift of rocks by layer, in which packs stratify the array, is shifted parallel to the contacts of rocks. Based on the deposits, this zone causes them to stretch and tilt without breaking the continuity with the formation of a zone of smooth shifts of the earth's surface.

Of all the forms of displacement of rocks on the earth's surface, the greatest danger is the cone of the collapse, which is formed suddenly. The sudden collapse of the earth's surface indicates the uncontrolled destruction of the safety pillars of underground chambers, which almost always leads to major accidents in mining. Timely filling of the produced space of blind deposits (deposits that do not reach the daily surface) with an mine rock (rock that does not contain iron of the required concentration) through mining workings or specially drilled wells prevents the formation of a collapse zone over the produced space and eliminates the formation the cone of the collapse.

The filling of the produced space of deposits by the bypass of the collapsed rocks and the filling of the collapsing funnels influences the process of shift and prevents the increase of the collapse zone and thereby prevents the occurrence of other cones of collapse.

According to the influence on the process of displacement of rocks and the earth's surface, the development systems in the Kryvyi Rih Basin are divided into three groups: collapsed, chamber, with the goaf stowing. When using ore collapsing systems and host rocks, the displacement parameters are determined by other influencing factors. Chamber development systems delay the displacement process but do not guarantee the appearance of dangerous landslides and deformations of the earth's surface if the system parameters do not ensure the stability of the host rocks.

The use of development systems with the goaf stowing by filled materials makes it impossible to form a zone of the collapse of rocks, funnels, dips, large cracks on the earth's surface. The parameters of the displacement process, in most cases, depending on the size of the placed deposit, the angle of its fall, the completeness of filling the space produced and the quality of the laying mixture. As evidenced by the practice of using systems with a goaf stowing by hardening materials at the mine "Ekspluatacyjna" (PJSC "ZAPORIZKYI IRON-ORE PLANT"), the disturbance of the earth's surface within the mine field is not observed.

The peculiarity of the systems of development with the goaf stowing is the filling of its stowing material gradually with the advancement of the cleaning recess. This system used to prevent the displacement of the earth's surface after the ore blocks have been extracted and sometimes to create favorable conditions for working out the safety pillars. The relatively poor performance of these systems has caused their system to

be replaced by collapsing host rocks. However, as mining goes down to great depths and the danger of displacement of the earth's surface increases, the value of stowing systems begins to increase, because at high mountain pressure the laying is the most effective and sometimes even the only possible means of maintaining the mountain range.

The following conditions of use are most characteristic of systems with the goaf stowing:

1. Low capacity of ore deposit – from several centimeters to 6 m. This explained by the fact that the required amount of laying material can be obtained by carrying out main and development workings for laying the produced space of small width.

2. Large angle of the ore deposit. A gentle fall complicates the placement of the stowing material in the working excavation.

3. Resistant ores that allow for a particular time to maintain the waste space unbound.

4. Unstable mine rocks. Because tough ores with stable host rocks can work out with more productive development systems.

5. A high value of ore due to the considerable cost of its extraction.

Depending on the shape and constancy of the elements of the ore deposit, the conditions of application of different variants of systems with the goaf stowing are different. The following main groups can be distinguished:

- systems of development the horizontal slicing with the goaf stowing;
- systems of development the inclined slicing with the goaf stowing;
- overhand store systems of development with the goaf stowing;
- longwall systems of development with the goaf stowing;
- systems of development the strips the goaf stowing.

The sources of obtaining the stowing material have a significant influence on the structural elements of the system, the order, and the technology of the actual mining. There are systems for delivering stowing material from outer space and systems for receiving it within the developing block.

The basic requirements for the stowing material are as follows: the material should be cheap and easily transportable, not have a large shrinkage, be inert in the fire relation, not caking, and also when working the inter-chamber pillars, the material should be compacted and gain stability – to this end, cementing agents added to the stowing material.

Sand, crushed rocks obtained in the mine or quarry, from surface heaps, tailings of preparation plant, boiler, and metallurgical slag, etc. are used as the stowing material.

In most cases, the choice of stowing material determined by the way it transported and placed in the working excavation. On these grounds, the laying divided into dry-gravity, pneumatic, and hydraulic.

Dry crushed material, sand, tailings of processing plants, granulated slag, clay in the amount of no more than 15-20 % recommended for the gravity stowing.

For pneumatic laying, use crushed rocks of such granulometric composition: pieces of size 15-20 mm – 75-80 %; pieces of 0.5-15 mm size – 20-25 %. Clay content should not exceed 10-15 %.

For hydraulic laying, coarse-grained sands and desilted tailings of processing plants used. Great features are the stowing blend, which contains 60% quartz sand and 40% shale gravel with a particle size of not more than 20 mm. The total shrinkage of such material does not exceed 6-9%.

Depending on the material of the laying, the ratio of solid material and water accepted: for sand from 1:0.75 to 1:1; for more extensive material from 1:1.5 to 1:2.5. At Canada's mines, thick paste in the form of paste containing sand or desilted tailings of processing plants has become widespread. The presence of binders (clay, cement, etc.) in the stowing material gives it stability, and it allows even holding in the massif of laying workings without fastening. Such a hardened blend laying, called a "hardening laying", is gaining increasing use in mine shafts.

Given the risk of landslides and collapse of the earth's surface, structures and natural objects are protected concerning their importance, structural features, resistance to deformation, nature of the operation, condition, service life, etc. To increase the effectiveness of security measures, all objects are divided into separate categories, which are shown in the table 1.

To protect residential, public, and industrial buildings that fall into areas of dips, terraces, and cracks, mountainous measures are applied, or warning and security targets remain.

In the area of smooth landslides of the lying side of the deposit, it is allowed to preserve structures and buildings by applying constructive protection measures, which are selected according to the recommendations for designing measures to protect structures and buildings from the influence of mining.

Roads (motorways and access roads), tram lines, motorways, 110 kV transmission lines and below, lines and cables, ground pipelines, etc., which allow eliminating the accumulated deformations are allowed to remain in areas of smooth landslides and cracks, but in projects must justify the repair, restoration, and monitoring of the surface in these areas.

All security measures must be approved by the organizations that operate the facilities. The main recommendations of the State Commission for Investigation of the Consequences of the accident, which occurred on June 13, 2010, at the Ordzhonikidze mine, are as follows:

1. Given the complexity of the mountain-geological conditions of the deposit "South-Magnetite", to clarify its physical and mechanical properties.

2. Develop a standard passport of the development system, taking into account the physical and mechanical properties of the deposit "South-Magnetite".

3. To revise the project "Measures for the protection of buildings, structures, and natural objects from the harmful effects of underground mining".

4. To carry out constant control on the part of the general designer on the observance of design decisions and schedules of working out of mineral reserves.

5. Undertakings carrying out underground workings shall introduce variants of development systems with a bookmark of the produced space from the beginning of operation of the field.

6. Perform scientific research to determine the effectiveness of methods of monitoring the state of the mountain during the development of deposits.

Table 1. Categories of objects located in hazardous areas shift of mining companies.

Protection category	Protected objects
I	1. Structures of the lifting complex of mines: trunks, nettles, buildings, and chambers of lifting machines. 2. Central compressor station. 3. Railways, railway stations. 4. 3-floors and more residential buildings. 5. Public buildings (schools, theaters, clubs, hospitals, etc.) 3 floors and more. 6. Industrial workshops with crane equipment with a capacity of more than 15 tons. 7. Supports of high-voltage power lines with runs between them of 300 m or more. 8. Railway bridges with runs over 20 m. 9. Water mains and pumping stations.
II	1. Ventilation and auxiliary shafts of mines, buildings of the lifting complex and fans. 2. Main lifting shunts, drifts, main lifting chambers, warehouses of explosive materials, electric locomotives. 3. District electric and compressor stations. 4. Mines railway depot. 5. Mining electromechanical workshops. 6. Mine processing factories. 7. Administrative and household plants and residential two and 3-floor buildings. 8. Public double floor' buildings (schools, hospitals, clubs). 9. Water towers more than 20 m high. 10. Boiler rooms. 11. Industrial workshops with crane equipment with a capacity of up to 15 tons. 12. Concrete loading bins.
III	1. Preparatory and threaded workings. 2. One-floor residential buildings, industrial and office buildings. 3. Access mines railway tracks. 4. Local transmission lines. 5. Telegraph and telephone lines. 6. Highways. 7. Collective gardens and parks. 8. Cemeteries. 9. Overpasses of open warehouses. 10. Mines mechanical workshops. 11. Natural and artificial reservoirs. 12. River beds. 13. Water towers up to 20 m high. 14. Ground pipelines.

Conclusion

1. During the development of the deposit “South-Magnetite”, there was no proper control over the condition of the produced space by the scientific and design organizations, as well as by the management of the Ordzhonikidze mine.
2. The project for carrying out the mass explosion on June 13, 2010, at the Ordzhonikidze mine was not mentioned in the list of documents analyzed by the state commission. This project should develop all measures for the security of a mass explosion, including the designated locations of security posts and the location of private and business vehicles.
3. Lack of security posts at the approaches to the area of the mass explosion could lead to more terrible consequences of this accident (getting into the area of an explosion of outsiders from surrounding villages, cars, other transport).
4. The main responsible person for the consequences of the accident is the owner of the enterprise, which is stipulated by the Law of Ukraine “On Occupational Safety”, the Mining Law of Ukraine, the Rules of Safety during the development of deposits in an underground way [10, 11, 12], whose name is not included in the state commission report which indicates the imperfection of its conclusions.

Abstract. Intensive development of the mining and metallurgical complex results in considerable volumes of waste materials, more than half of which are produced by mining enterprises. Modern mining and processing can provide non-waste production only if mineral extraction and grade recovery from natural and technogenic mineral materials are regarded as a single technological process and the Earth surface preservation becomes a priority in determining parameters of process integration. The research is aimed at improving of the technology of metal leaching in a disintegrator through complex application of metallic ore concentration tailings. A radical step of reducing mining waste hazards is their utilization through introducing technogenic reserves of metallic ore concentration tailings into production, thus creating a new raw material base for the mining industry. Substantiation of the concept of non-waste utilization of off-grade mineral materials depends on the amount of integration of chemical leaching and mechanochemical activation in the disintegrator and is achieved by means of modern information technologies.

1 Introduction

Mineral extraction is characterized by increasing volumes and areas of mining operations aimed to satisfy humanity's growing needs [1-5]. It results in accumulation of aggressive wastes at all process stages accompanied by intensive impact on the environment causing costly preventive measures (Fig. 1).

Fig. 1. Control chart of environmental conditions with regard of waste utilization

Tailings of mineral treatment are almost not applicable and hazardous to store, yet their rational use can provide great economic efficiency [6-8].

Man-made deposits result from changed requirements to marketable ores, selective extraction of rich deposit sites and increased volumes of pillars under complicated conditions of filling voids with consolidating mixtures [9-10].

The volume of reprocessed mineral wastes does not exceed a few percent of the total mineral output. It is explained by the fact that technologies applied do not enable extracting useful components from waste materials. Currently, each technology of ore mining and processing is characterized by some economically reasonable limits of extraction conditioned by mining parameters [11-13].

This approach complicates sustainable use of natural resources and cannot be changed at present. Methods of control intended to improve resource use and decrease man-made wastes can solve the mentioned problems [14-17].

Intensive development of mining and metallurgical complexes results in accumulation of considerable amount of wastes, more than half of which is produced by the mining industry [12, 18-20]. Many scientific works deal with technological solutions of waste utilization problems [21-24].

At the same time, the degree of efficiency of utilized wastes is extremely low [25-26]. Only 15% of large ore deposits consider mining and treatment wastes as part of their technological cycle. Industrial wastes are mostly used as construction materials and to manufacture consolidating mixtures.

According to modern ideas, wastes can include natural, man-made and natural-technogenic resources (pillars). Man-made deposits are formed without considering their subsequent reuse. Although, there are some man-made deposits designed to ensure certain technological, geomechanical and physical-mechanical

* Corresponding author: morkunv@gmail.com

parameters necessary for their future re-treatment.

Mining and processing enterprises can be waste-free only if issues of extracting minerals from the Earth's interior and valuable components from natural and man-made mineral materials are considered as a single technological complex and the Earth surface preservation becomes a priority in determining parameters of process integration.

In mining, complex waste utilization provides for deep re-treatment of man-made materials accompanied by extracting gold, platinum, palladium, silver, non-magnetic hematite and other useful components as well as removing heavy metals and radionuclides to meet sanitary requirements (Fig. 1).

In developed industrial countries, utilization of industrial wastes reaches 70%. In the USA, for example, 20% of aluminum, 33% of iron, 50% of lead and zinc and 44% of copper are produced as a result of re-processing mine wastes. In the state of Montana (USA), 2 t of gold and 4 t of silver are obtained annually at waste dumps with 0.84 g/t of gold and 2.8 g/t of silver content. In Michigan (USA), 60% of copper is extracted from mill tailings with 0.3% copper content [1-3, 20-24].

Every year, in the RSA, 3.5 t of gold and 700 t of uranium are produced at waste dumps of gold mining mills with 0.53 g/t gold and 40 g/t uranium content, average productivity making 50 000 t/day. The same trend is observed in Canada, Great Britain, Spain and other countries [11, 20-24].

When recycling industrial wastes, the cost of marketable products is 10-15 times less than those produced by conventional methods. Therefore, development of this trend can result in profits comparable with basic production [27-30]. For instance, recycling 150 million ton of concentration wastes of manganese ores of Nikopol region and 500 million t of concentration wastes of Kryvyi Rih iron ores can result in manufacturing products that worth 5-7 billion USD. To update tailings recycling, there are used methods of magnetic, gravity and electrochemical separation and concentration of off-grade materials. They allow extracting such basic waste components as iron, manganese, titanium, sulphur and silica by applying magnetic separation and sorting them into selective marketable products, thus making separation and concentration of the rest waste materials by gravity methods highly effective [12-15].

Electromagnetic separation, flotation, gravity and other methods are applicable to concentrating industrial wastes and semi-finished products of steel mills [31-34]. For instance, flotation of copper and nickel is used at many national and foreign enterprises; pneumatic treatment of clinker – at some national enterprises; flotation of acid agglomerated cake resulting from cinder leaching – at zinc producing mills of Risdon (Australia), Kosaka (Japan) and Trail (Canada); retort residue jiggling – at the mill of Fridrich-August (Germany).

Conventional concentration technologies have some extraction limits resulting in tailings that become unfit for further use.

Mining conditions tend to deteriorate nowadays. Prospects of the mining industry and environmental safety should be assessed considering the fact that demands for

mining products are difficult to satisfy in spite of new deposits being developed.

Mineral treatment implies that from 30-40% to 99.9% of mined rock mass will turn into tailings. While expansion of tailings ponds result in destroyed vegetation and soils, increased height of tailings causes favorable conditions for dust dissemination and contamination of the biosphere of nearby areas. 20% of claim areas are occupied by rock piles, 13% – by tailings ponds of concentration plants, 5% – by dumps and wastes and 3% are turned into unfit for further use because of disturbed surface. About 0.1 ha of farming lands per 1 000 t of raw materials is expropriated for waste disposal [1-2, 11].

Almost all mineral deposits are located in areas of seismic activity. Tens and hundreds cubic meters of unfilled voids are created as a result of mining operations. The voids react to geodynamic and seismic changes in the region and can cause similar changes by themselves. Seismic safety of rock mass is a system of controlling the risks caused by seismic oscillations of various intensity in a given period of time.

Modern technologies preserving the lithosphere are based on principles of protecting the Earth's surface from disruption caused by mining operations thanks to controlling geomechanical balance of the rock mass in the course of mineral extraction and any time after it. They provide filling voids with consolidating mixtures and tailings of leaching metals from ores in situ.

The influence of mining on the Earth lithosphere is determined by sizes of mine fields and workings, areas of undermining, extraction volumes and the ratio of broken rock mass to the hoisted one.

Rich ore reserves localized in favorable conditions are not sufficient. Therefore, deeper levels of existing mines and former reserve deposits with complicated mining and geological conditions are going to be developed in the nearest future. It is associated with reduced metal content in mined ores, increased volume of waste materials and augmented load on the environment [12, 16-17].

Currently, mining production is characterized by scarce mineral reserves and escalated nature-man relationship. That is why, in choosing an efficient design, environmental damage and mineral losses in situ should be taken into account.

Accumulated tailings are caused by application of mechanical energy only in the majority of traditional technologies of concentration and metallurgy. Chemical leaching in percolators does not increase metal extraction, yet it takes longer time. Leaching in a disintegrator has recently appeared as a new technology [35].

Problem statement of the research is substantiation and analysis of the suggested technology of metal leaching in the disintegrator, which is aimed at integrated application of tailings of metalliferous ores concentration.

2 Materials and methods

Activation of a substance by great mechanical energy under the processing speed of more than 250 m/sec in the disintegrator results in electrically unbalanced charged centers in the material, thus radically changing mineral

properties. The mechanochemical technology enables production by 30% cheaper, saving 30% of energy.

This trend is unique and opens up potential for revolutionary changes in ore treatment, modern information technologies ensuring its advantages by:

- application of computer-aided methods to control parameters of a process;
- versification of design variants;
- development of calculations and machine-language programs;
- development of simulation design complexes.

Efficiency of the mechanochemical technology can be proven experimentally. The first step of its substantiation is formalization of experiment requirements.

The following variants of extracting metals from mill tailings of various ores are compared: basic agitation leaching; agitation leaching after activation in the disintegrator; leaching in the disintegrator.

While conducting an experiment according to Venken-Box mathematical planning, the following independent factors are determined: sulfuric acid content in the solution (X_1) of 2-6-10 g/l; sodium chloride content in the solution (X_2); ratio of the leaching solution mass and that of tailings (X_3); time of leaching (X_4) within 0.15-0.625-1.0 h.

Tailings of complex ores of Sadon deposit (the Republic of North Ossetia – Alania) contain, %: zinc – 0.95; lead – 0.84; silver – 0.015; copper – 0.18; manganese – 0.015, etc. Reagent leaching in the disintegrator results in almost similar extraction of metals as compared to separate activation in the disintegrator, yet it reduces the process duration by 2 orders of magnitude. In the decreasing order, the process is affected by the reagent content in the leaching solution, disintegrator RPM, the number of treatment cycles, and mass ratio of the leaching solution and tailings.

Regression analysis of the research results provides the following mathematical models:

$$\begin{aligned} \varepsilon = & a_0 + a_1X_1 + a_2X_2 + a_3X_3 + a_4X_4 + \\ & + a_5X_{12} + a_6X_{22} + a_7X_{32} + a_8X_{42} + a_9X_1X_3 + \\ & + a_{10}X_1X_4 + a_{11}X_2X_3 + a_{12}X_2X_4 + a_{13}X_3X_4, \end{aligned} \quad (1)$$

where X_1 is H_2SO_4 content in the leaching solution, g/l; X_2 is NaCl content in the leaching solution, g/l; X_3 is the ratio of solid and liquid phases; X_4 is RPM of the disintegrator, Hz.

The determination factor for the zinc extraction dependency makes $R_2=0.85851$, for lead extraction dependency $R_2=0.78037$, for iron extraction dependency $R_2=0.94587$.

To achieve objective assessment of changes in dependencies, the graphic-analytical method is applied. To present changes of extraction values of larger groups of metals, there are diagrams of dependencies of metal extraction on each predictor, while the values of the three left predictors are averaged, i.e. for $X_1=6$ g/l, $X_2=90$ g/l, $X_3=7$, $X_4=125$ Hz (Fig. 2-5).

The dependencies are continuous and are characterized by flex and extremum points in the diagram indicating accuracy of mechanochemical activation for leaching metals in the disintegrator. Dependencies

between studied parameters of multi-grade materials and indices of metal extraction can be used to find optimal parameters in solving optimum problems by IT methods.

Fig. 2. Dependency of metal extraction in the solution on sulfuric acid content in the leaching solution: Series 1 is zinc extraction $\varepsilon = -1.1144 X_{12} + 16.942 X_1 - 3.4359$; Series 2 is lead extraction $\varepsilon = -0.3352 X_{12} + 3.2464 X_1 + 44.31$; Series 3 is iron extraction $\varepsilon = 0.0529 X_{12} - 0.115 X_1 + 1.4897$.

Fig. 3. Dependency of metal extraction in the solution on salt content in the leaching solution: Series 1 is zinc extraction $\varepsilon = 0.002 X_{22} - 0.6422 X_2 + 99.776$; Series 2 is lead extraction $\varepsilon = -0.0048 X_{22} + 1.0994 X_2 - 8.345$; Series 3 is iron extraction $\varepsilon = 0.0002 X_{22} - 0.0222 X_2 + 3.14$.

Fig. 4. Dependency of metal extraction on the ratio of solid and liquid phases: Series 1 is zinc extraction $\varepsilon = -0.2466 X_{32} + 5.062 X_3 + 34.75$; Series 2 is lead extraction $\varepsilon = -0.2603 X_{32} + 3.5523 X_3 + 39.61$; Series 3 is iron extraction $\varepsilon = -0.0282 X_{32} + 0.5917 X_3 - 0.0553$.

3 Results and discussion

The developed concept of waste-free treatment of off-grade mineral materials includes the following principles:

1. Conventional concentration does not provide full exposure of minerals and cannot be applied to deep extraction of minerals from mill tailings.

2. There is a promising trend of improving extraction of minerals from off-grade mineral materials by combining chemical leaching and mechanical activation in the disintegrator where the leaching solution is pressed into formed cracks facilitating the extraction rate which is inaccessible for traditional technologies.

3. Parameters of mechanochemical leaching of components from metal-bearing raw materials are subjected to forecasting on the basis of experiments by unified methods of formalizing requirements.

Fig. 5. Dependency of metal extraction on intensity of mechanical activation or RPM of the disintegrator: Series 1 is zinc extraction $\varepsilon = 0.0003 X_{42} - 0.0555 X_4 + 60.038$; Series 2 is lead extraction $\varepsilon = 0.0004 X_{42} - 0.1215 X_4 + 60.658$; Series 3 is iron extraction $\varepsilon = -0.00002 X_{42} + 0.0122 X_4 + 1.5468$.

Environmental and economic efficiency of the modern mining complex should be characterized by minimal material, energy and other expenses to produce marketable products and prioritize preservation of ecosystems and sustainable mineral use. When determining profitability of mineral mining, one should consider mined resources that are not turned into marketable products and become lost.

The model of efficient use of off-grade mineral materials contained in mill tailings looks like [13]:

$$\sum_{t=1}^{t_{bp}+t_p} \Pi_{prt} = \sum_{t=1}^{t_p} A_t (Z_{mt} - C_{mt}) \frac{1}{(1+E)^{t-1}} + \sum_{t=1}^{t_c} K_x (1+E_n)^{t_c} + \gamma_x \left[\sum_{t=1}^{t_p} A_{pt} (Z_{mrt} - C_{mrt}) - \sum_{t=1}^{t_{bp}} K_{dat} (1+E_c)^{t_{bp}} \right], \quad (2)$$

where γ_x is the yield of off-grade materials, unit fraction; A_t is production capacity of an enterprise in the t -th year, t/year; t_p is a rated period of application of a technical design, years; t_{pba} is a period of building auxiliary facilities for re-treatment, years; t_c is a period of construction, years; Z_{mt} and C_{mt} are the extracted value of mined rock mass and expenses for mining and processing in the t -th year, UAH/t; K_{xt} construction investments in the t -th year, UAH; A_{pt} is production capacity of an enterprise for off-grade materials retreatment in the t -th year, UAH/t; Z_{mrt} and C_{mrt} are the value extracted from off-grade materials and re-treatment costs in the t -th year, UAH/t; K_{dat} is expenses for constructing and developing auxiliary facilities in the t -th

year, UAH; E is the factor of discounting expenses and profits in terms of time, unit fraction; E_c is a bank-credit interest for performing auxiliary operations, unit fraction.

The environmental and economic model of efficiency of off-grade materials re-treatment by the maximum profit criterion and considering the region environment is the following:

$$\Pi = \sum_{p=1}^P \sum_{o=1}^O \sum_{r=1}^R \sum_{t=1}^T \sum_{f=1}^F \sum_{n=1}^N \{ (M_{ey} Z_{my} + Q_y Z_{qy}) \} - \sum_{w=1}^W [K (1+E_{ny}) + E_q + E_x] - [(M_c Z_m + QZ_q) + Q_g Z_g] \times \times K_c K_y K_t K_b K_g K_{vr} K_{ch} \rightarrow \max \quad (3)$$

where P is utilization products; Q is types of off-grade materials; R is re-treatment processes of off-grade materials; T is re-treatment time; F is phases of existence of a mine and a plant; N is a stage of off-grade material utilization; W is expenses for off-grade materials utilization; K is capital investments for arranging a utilization site; K_c is a self-organization factor of off-grade material storages.

The mathematical model of leaching metals from ores correlates to conditions and technological features of metal extraction described by regression dependencies and subjected to forecasting.

The complex composition of mill tailings containing the first and the second hazard class substances does not enable their utilization without waste neutralization. Available technologies of re-treatment cannot extract valuable components under their low content to meet required sanitary standards.

Tailings re-treatment can make the need to store utilized tailings on the surface redundant and corresponding lands can be returned into farming use [36].

Metal-bearing tailings can be re-treated only in case of metal extraction according to sanitary standards. Mechanochemical re-treatment is able to meet these requirements. Tailings of mechanochemical activation of mill wastes are a dispersed mass of particles about 0.1 mm in size noted for a more uniform structure, which facilitates re-treatment quality.

In re-treatment of man-made deposits, there are used off-grade reserves, the amount of which is comparable with initial reserves of large deposits. If there are available capacities to utilize off-grade materials, it becomes efficient as expenses for their retreatment are already amortized.

The economic effect of developing man-made deposits includes increased extraction of metals with minimal production expenses and re-treatment stages to obtain a marketable product.

The maximum economic effect of introducing innovative technologies is achieved due to increased mineral reserves, production conversion and extended life-cycles of deposits.

To compare technologies with different mineral extraction rates, it is necessary to assess losses of minerals in comparable units of measurement. When evaluating

losses, it is reasonable to analyze the lost value of components determined by the limit prices of the industry. It enables the single criterion of the technology - profits allowing for damage by mineral losses both in situ and tailings.

Putting wastes of no industrial use into operation has a great impact on the amount of extracted reserves and metal content of the mined ore, thus reducing operational costs and improving efficiency of investments and production assets.

Elimination of the need to store tailings on the Earth's surface can ensure profits by selling re-treatment products, returning lands into economic use and improving the region's environment.

Conclusions

Metal-bearing mine wastes accumulated on the Earth's surface present a global problem that can be solved by their utilization which turns hazardous off-grade materials into a valuable resource.

Human demands in metals can be satisfied by using concentration tailings as a new raw material base of the mining industry, thus solving the problem of deficiency of some metals. Substantiation of the concept of the waste-free re-treatment of off-grade mineral materials depends on combining chemical leaching and mechanochemical activation in the disintegrator treated as a single technological cycle.

Scientific novelty is that for the first time, the method of improving efficiency of the technology of leaching metals from the currently substandard mineral materials through combining chemical leaching and mechanical activation in the disintegrator where the leaching solution is pressed into the cracks resulted from particle destruction has been substantiated, this providing for efficient speed of recovery impossible under the traditional technology.

There are three variants of recovery of metals from ore concentration tailings of various types: basic agitation leaching, agitation leaching after activation in the disintegrator and leaching in the disintegrator.

It is demonstrated that in comparison with separate activation in the disintegrator and leaching outside the disintegrator, reagent leaching in the disintegrator provides almost the same metal recovery, yet it reduces duration of the process by two orders of magnitude. It is determined that the process is affected by the following factors in the descending order: reagent content in the leaching solution, rotor frequency in the disintegrator, the number of processing cycles in the disintegrator and the mass ratio of the leaching solution and tailings.

The regression analysis of the experiment results provides for mathematical dependencies of metal recovery on the content of H_2SO_4 and $NaCl$ in the leaching solution, liquid-solid phase ratio, and rotor frequency of the disintegrator. The determination factor for the zinc recovery dependency makes $R^2 = 0.85851$, that of lead recovery is $R^2 = 0.78037$, and that of iron recovery is $R^2 = 0.94587$.

The study of the stress-strain state of the massif in mining uranium at “VOSTGOK” deposits

Mykola Stupnik, Vsevolod Kalinichenko, Mykhailo Fedko, Olena Kalinichenko, and Mykhailo Hryshchenko*

Kryvyi Rih National University, Department of Underground Mining of Mineral Deposit, 11 Vitalii Matusevych Str., Kryvyi Rih, 50027, Ukraine

Abstract. Being one of the world's largest uranium producers (about 2% of the world's production), the state enterprise “Vostochnyi Mining and Processing Works” (“VostGOK”) provides about 40% of Ukraine's nuclear power stations with uranium raw materials. Considering the conditions of uranium deposits exploitation (location in densely populated areas, protected sites etc.), to protect the environment from possible emissions of radioactive elements room mining is applied with subsequent backfilling of the dead area with consolidating mixtures. This technology is economically reasonable at deposits with the increased uranium content. To exclude a number of labour-consuming and environmentally dangerous operations from the production process, lean uranium-containing ores are reasonable to be mined applying underground block leaching. This enables reaching maximum values of mineral extraction and avoiding considerable material expenditures on backfilling mixture preparation and backfilling dead rooms, as they are almost completely backfilled with the muck pile, and on utilization of waste after the mined ore primary processing (barren rocks and off-balance ores) on the daylight surface.

1 Introduction

Further cut of costs can also be achieved through mining deposits by vertical double blocks. Ore body 10 of the Michurinskoye deposit is supposed to be mined in blocks 10-2 and 10-3 at the 325-184 m level at the Ingulskaya mine (Fig.1).

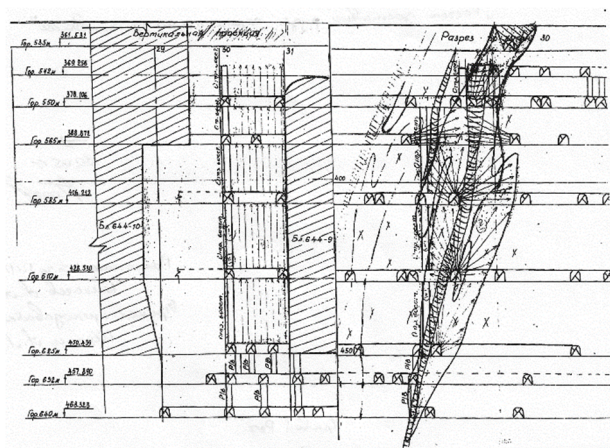

Fig. 1. The vertical plane of blocks 10-2 and 10-3 (ore body 10 of the Michurinskoye deposit).

The process is as follows. Another room is located under the temporary pillar-crown below the dead room backfilled with the muck pile. Under this pillar in the block located further down the dip angle compensatory

room is placed to which reserves of this block are broken and the temporary crown is brought down. The solution for leaching uranium ores is fed from the existing workings over the room of the upper block. At this, volumes of mining are cut and pipes are again used for feeding the working solution to blocks [1-3].

The levels of stress in main structural units and in the enclosing rock massif, the condition of the roof bar (the degree of its disturbance caused by workings and deep shafts) are different from those occurring when the traditional technology is applied. Besides, the crown is affected by reagents for underground block leaching. Due to all that, factors impacting the crowns stability and mine safety on the whole require urgent investigations.

Determining permissible dimensions of main structural element of room mining systems [main regulatory documents [1, 2] however, do not consider the influence of the ore bed dip and are not intended for determining the safe thickness of a roof. The technology of underground block leaching of uranium ores in vertical double blocks is a new one to be applied at VostGOK underground mines and requires scientific support [4-7].

To study the stress-strain state and stability of crowns depending on the dip of ore bed and the conditions of the above mentioned blocks, mathematical modelling applying the finite-element technique was applied. The range of boundary conditions of the impacting factors included values characteristic of all the underground mines of “VostGOK”. Uranium ore hardness varied from 9-11 to 14-16 on the Protodyakonov scale, that of the enclosing rock - 13-15, the dip of ore body made from 60°

* Corresponding author: Michael.grischenko@gmail.com

to 90°(in increments of 10°). The stress-strain state was calculated for roofs of 10 to 14 m thick. For calculating the stress field characteristics ANSYS 18 was used [8-10].

The results of modelling the stress-strain state of 10 m thick roofs in ores of various hardness with the ore body dip angles of 90°, 70° and 60° are presented in Fig 2, 3 and 4 [11].

2 Methods

As is seen, the tension stress zone in the lower central part of the crown is the most dangerous. This corresponds to the classical concepts of stress field development in the so called “stress relief arch” that occurs when the massif is undermined by the lower block room. As ore hardness reduces, absolute values of stress in the crown decrease slightly (by 0.1...0.5 MPa, i.e. from 1...2 to 6...7%). This can be explained by the fact that less hard ores are less liable to accumulate stress as they get relieved through deforming towards a post mining voids (i.e. the room) and, on the opposite, harder ores tend to accumulate stress due to smaller deformations. However, stability of less hard ore crowns decreases due to reduction of their ultimate strength [12-14].

For instance, with the ore body dip angle $\alpha = 90^\circ$ and hardness of 14-16, the value of tensile stress in the lower part of the crown reaches 10.1 MPa (Fig. 2, a). However, as ultimate tensile stress of such ores is about 11 MPa, these stresses will not cause failures.

When the crown is made of ores of 10-11 points (Fig. 2,d), the tensile stress level makes 9.9 MPa. With the ultimate strength of the ores of 7.7 MPa this will cause rock falls of about 100...150 m³ (according to “Instructions...” [15] used at “VostGOK” mines, rock falls of over 250...300 m³ are considered critical).

With the dip angle $\alpha = 70^\circ$ and ores of 14-16 points roof failures do not practically occur (Fig. 3, a), with $\alpha = 60^\circ$ small rock falls (3-5 m³) may occur even in crowns of ores of the same hardness (Fig. 4, a). In roofs of ores of 10-11 points with $\alpha = 70^\circ$ (Fig. 3, b) and $\alpha = 60^\circ$ (Fig. 4, b) the volume of rock falls will make from 150 to 200...220 m³, sometimes to 400...450 m³ respectively [16-18].

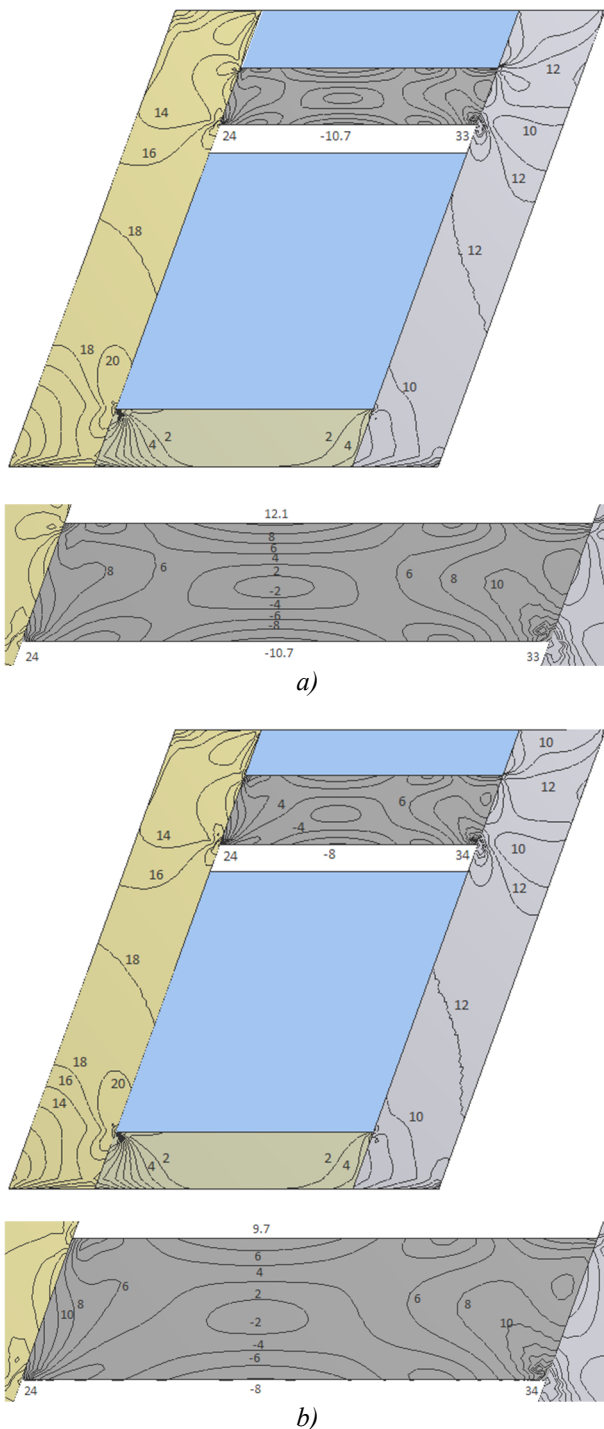

Fig. 3. Stress field development in 10 m, 12 m, 14 m crowns with the ore body dip of 70° , MPa.

These values testify to the critical condition of the crown at angles about $\alpha = 70^\circ$, at about $\alpha = 60^\circ$ the crown will fail.

Thus, the obtained results testify to the considerable impact of the ore body dip angle on the stress-strain state of crowns and their stability and enable us to suggest application of the correction factor K_α , whose numerical values are given in Fig. 5. [19-22] So, when determining the minimum permissible thickness of the crown in certain conditions, its value obtained without this factor should be corrected through multiplying it by the corresponding value K_α [23-26].

Changes in the existing stress fields, increase of absolute values of current stresses caused by technological workings result in decrease of the crown stability.

Due to this, when determining safe dimensions of exposures and pillars, they should be corrected considering the accepted criteria. In the first case, the crown thickness is determined according to conditions of the room mining order in compliance with the instructions developed by NIGRI (Research Ore Mining Institute) [27]. In the second case, the correction factor is applied.

We suggest correcting thickness of the crown with workings using the expression

$$h_{cr}^n = h_{cr} \cdot K_{dist}, \text{ m}; \quad (1)$$

where h_{cr} is thickness of the monolith crown, m; K_{dist} is the factor considering disturbance of the crown resulted from mining, unit fraction [28-31].

As the disturbance degree of the crown depends on the number of workings in it, their geometrical dimensions and thickness of the crown itself, we suggest determining the numerical value of K_{dist} as the product of separate

universal factors [32-35]. Each of these factors differentially takes into account the impact of a particular working on the crown stress-strain state and, consequently, on its stability, as follows

$$K_{dist} = K_1 \cdot K_2 \cdot \dots \cdot K_n, \text{ unit fraction}; \quad (2)$$

where K_n is the number of workings in the crown.

Numerical values of these factors calculated individually for each working can tentatively be determined as follows

$$K_i = \sqrt{1 + (h_i^w / h_{cr})}, \text{ unit fraction}; \quad (3)$$

where h_i^w is the i -th working height (width), m.

For instance, according to the calculations, the minimum permissible thickness of the crown not disturbed by workings is $h_{cr} = 10$ m. In case of workings of 2.5, 3.0, 3.5 and 4.0 m, the correction factors for each of them determined by (3) will equal 1.12, 1.14, 1.16 and 1.18 respectively.

Fig. 4. Stress field development in 10 m, 12 m, 14 m crowns with the ore body dip of 60°, MPa.

Fig. 5. K_{α} values depending on the ore body dip angle α .

Thus, the crown thickness should be increased to 11.2, 11.4, 11.6 and 11.8 m respectively [36-39].

If there are 2 workings of 3.0 m and 3.5 m in the crown, the correction factor will make $K_{dist} = 1.14 \cdot 1.16 = 1.32$. Correspondingly, the disturbed crown thickness should be increased to 13.2 m [40, 41].

If there are 3 workings of 2.5 m, 3.0 m and 3.5 m in the crown, the correction factor will make $K_{dist} = 1.12 \cdot 1.14 \cdot 1.16 = 1.48$. Under such conditions the crown thickness should be half as much as that of the monolith crown and make 14.8 m.

3 Results and discussion

So, the crown thickness should be corrected considering decrease of its stability caused by workings. This will help avoid its complete or partial failure.

As shrinkage stoping with sulphuric acid treatment is one of the main components of underground block leaching of uranium ores, the crown separating the rooms will also be exposed to the sulphuric acid.

The research conducted enables the authors to assume that the longstanding (from 3-4 to 6 months) exposure to the sulphuric acid may negatively impact strength properties of the ore massif of the crown. This assumption is substantiated by data on the physical and mechanical properties of rocks of the Michurinskoye deposit, particularly albitites and migmatites which are the most representative rocks in uranium ore occurrence zones. Thus, the average compressive resistance of rocks in their natural humidity conditions and when water-saturated makes 164.4 MPa and 127.5 MPa for albitites and 153.1 and 112.4 MPa for migmatites respectively. That is, if compared with the natural state, water saturation of rocks reduces their compressive resistance by 22...27%.

The analysis of the data on the physical and mechanical properties of rocks of the Michurinskoye deposit, particularly albitites and migmatites which are the most representative rocks in uranium ore occurrence zones, enables the authors to conclude that the longstanding (from 3-4 to 6 months) exposure to the sulphuric acid may negatively impact strength properties of the ore massif of the crown. The average compressive resistance of rocks in their natural humidity conditions and when water-saturated makes 164.4 MPa and 127.5 MPa for albitites and 153.1 and 112.4 MPa for migmatites respectively. That is, if compared with the natural state, water saturation of rocks reduces their compressive resistance by 22...27%.

The impact of the sulphuric acid solution on the crown stability was confirmed by the following investigation. Forty ore cubes with 50 mm sides were divided into two groups. The first group of 10 cube shaped samples was used to determine the uniaxial compressive resistance in the natural conditions, the remaining cubes were used for determining the degree of the sulphuric acid solution impact on the samples' strength.

To provide conditions of the crown contacting the acid solution, in the laboratory environment only one face of an ore sample contacted the acid solution. The other faces of the cubes were covered with two coatings of paraffin. These cubes were placed in a vessel with the sulphuric acid solution which is used for spraying the shrunk muck pile in underground mines of "VostGOK". Tests of uniaxial compressive resistance were carried out 2.5, 4 and 6 months after dipping to determine the impact of the exposing time on the uranium ore strength. These periods correspond to the minimum and maximum time of the reagent impact in real conditions.

The laboratory hydraulic press is able to produce pressure up to 50 t. In relation to the cubes' surface $S = 25 \text{ cm}^2$ the corresponding pressure makes about 2000 kg/cm², or 200 MPa. The press is coupled with a computer that sets the loading rate for the samples and forms the loading diagram for each of the samples with the automatic recording of the current load, maximum pressure at the moment of their destruction and calculates ultimate strength of each sample depending on its sizes. During the tests the minimum loading rate of 1 kN/s was set according to corresponding standards (from 1 to 5 kN/s).

The samples of the first group demonstrated the average value of the uniaxial compressive resistance of

about 130 MPa. According to the instructions [42] this value corresponds to the rock hardness ratio of 11 points. For the samples exposed to the sulphuric acid solution during 2.5, 4 and 6 months, average strength values made 82...84.5, 79.5...80.5 and about 78 MPa respectively, i.e. their ultimate strength decrease (in relation to the samples of the first group) made 35...37%, 38...39% and about 40%.

4 Conclusions

Thus, the tests conducted confirmed the authors' assumption about the considerable impact of the acid solution on the uranium ore strength and, consequently, the stability of exposures and pillars. The determined dependencies should be considered in defining the safe crown thickness when applying the technology of underground block leaching of uranium ores.

So, the research conducted enabled determining the degree of impact of major factors (ore body dip, crown integrity loss caused by technological workings, impacts of reagent used when applying underground block leaching of uranium ores) on the crown stability. These factors should be taken into account when determining safe dimensions of exposures and pillars using corresponding correction factors. As a result, in concrete conditions it is necessary to correct parameters of structural units of blocks, particularly the crown thickness, considering the value of its stability changes caused by the above factors. This correction enables avoiding the crown failure and provides safety of works. The determined dependencies can then be corrected considering practical experience of "VostGOK" underground mines.

So, the research conducted has resulted in the following:

- the degree of impact of major factors (ore body dip, crown integrity loss caused by technological workings, impacts of reagent used when applying underground block leaching of uranium ores) on the crown stability has been determined;
- the factors should be taken into account when determining safe dimensions of exposures and pillars using corresponding correction factors.
- in concrete conditions it is necessary to correct parameters of structural units of blocks, particularly the crown thickness, considering the value of its stability changes caused by the above factors. This correction enables avoiding the crown failure and provides safety of works.

The determined dependencies can then be corrected considering practical experience of "VostGOK" underground mines.

Abstract. The purpose of this study is to establish the mechanism of interaction between stresses and strains and their quantitative values at the intersection of stopping and development headings to optimize methods for controlling the behaviour of the rock massif. The research complex includes priority methods with experimental confirmation of the calculated parameters by geophysical studies, including stress calculation by a sensor system and surveying levelling to measure deformations using support frames. The properties of the massif and the role of faults and macro-cracks in the development of a field of a complex structure are systematized. A method for studying the stresses and deformations of rocks at the intersection of stopping and development headings is given. The patterns of the rock massif behaviour at the point of intersection are established. The article provides quantitative values of changes in the physical and mechanical properties and stability of rocks at the point of intersection. Massif was differentiated according to the magnitude of the effective stresses in different phases of the intersection. Stresses for specific conditions were calculated with the determination of the reliability of the mining site. The patterns of change in stresses and strains in time are noted.

1 Introduction

The operated deposit is an underground structure with an internal arrangement and a system of elements. The construction parameters are calculated by methods of structural mechanics, which includes the principles and methods for calculating the strength, stiffness, and stability of structures. Structural mechanics is a tool for calculations related to the strength, stiffness, and stability of both individual elements and the structure as a whole [1-3].

The safety of underground structures is assessed by comparing the actual value of the risk with its value, established based on a situation analysis. For the sake of objectivity, comparable construction geotechnologies should be comparable in the maximum number of features: ore reserves, dip angle, ore and gangue rock characteristics, plant production capacity, and cost of operations. When comparing technology, the risk indicator can be determined by one main parameter, for example, by the bearing capacity of a structure from rocks exposed by mining.

The control effect on the strength of the system consists in the use of parameters at which the strength of the bearing rock structures is ensured by the residual strength of the rocks and the stresses of the lateral active rocks pressure, which can be increased by hardening the rocks.

Controlling the strength of the rock structures consists of the implementation of the residual bearing capacity of the rocks by limiting the size of the spans of the workings. Within geomechanically balanced areas, underground and construction geotechnologies minimized in terms of labour and materials costs can be applied.

The greatest danger to underground objects is the critical deformation of the rock mass in the case of insufficient strength of natural or artificially created supporting structures - pillars, which depend on the spans of exposure of the rock roof between the supports. The processes in the rock masses are stochastic, the initial information for solving the technical and economic problems in the mining industry is probabilistic, so the evaluation of the behaviour of the massif and its impact on underground objects is a serious problem, the relevance of which increases with the scale of the expansion of mining in the deep of Earth.

To increase the safety of natural-technogenic structures, the safety margin of the pillars is sought to be increased. This is accompanied by an increase in ore losses in the security pillars and an increase in the cost of materials for the construction of artificial supports.

The underground structural analysis employs general laws of mechanics and proportions that take into account the physical and mechanical properties of the rock mass, the conditions of the interaction of elements, parts, and structure base. According to the measurement results, a

* Corresponding author: morkunv@gmail.com

design scheme for the structure and a mathematical model in the form of a system of recurrent equations are formed. The advantages of structural mechanics in the mining industry include the ability to solve dynamic problems because the underground structure is a system operating under the influence of variable dynamic loads and force fields [4-6]. A prerequisite for the safe and efficient underground exploitation of mineral deposits is accounting for and using the properties of the ore-bearing rock massifs. The quality of the extracted raw materials and the number of expenses for managing rock structures depend on the completeness of property accounting; therefore, the dynamic of stresses and strains in the process of mining ores is the goal of field studies, including geophysical and surveying methods.

The safety and efficiency of mine development are ensured by preventing critical stresses in the elements of the ore-rock-ground system, arising from the interaction of man-made (caverns, explosion seismic, vibration, etc.) and natural (tectonics, gravity, seismicity) factors of field development. The increase in the depth of mining and the increase in mineral extraction enhances the scale of the impact on the ore-bearing massifs, the stability of which is the result of the interaction of the emerging force fields. The most dangerous conditions are created when the ore bed is intersected with workings.

The experience gained in controlling the properties of an array can be reduced to the following:

- in underground mining, fractured rocks have residual strength and are capable of creating supporting structures;
- the use of rock structures during mining is an effective way to improve the performance of underground and construction geotechnologies;
- the reliability of the control of rock masses state enclosing mountain objects is increased by using measures to adjust the sizes of structural blocks by technological means;
- the use of rock structures creates an economic effect, reducing losses entirely and improving the quality of mineral resources extracted, and reducing the cost of labour and materials for the control of rock pressure. The rocks of different ages in the geological structure of rock deposits are involved. The leading role in the structure and ore content of the deposit belongs to faults. Near the tectonic faults, the fracturing increases, reaching a maximum in the operating faults and near them.

The ratio of the dimensions of the permissible span by stability and the span of the collapsed arch becomes a priority safety criterion, especially when mining rocks over a large area, for example, with the leaching of metals from ore deposits. The most dangerous phenomena in the form of loss of stability or dynamic forms of rock pressure occur when the ore is excavated in areas of articulating structural disturbances composed of strong but fractured and weakened rocks. The behaviour of rock masses during development depends on the interaction of natural and technical factors. Natural factors include, first of all, the stresses acting in it at different periods. Research in this area is aimed at predicting the development of rock pressure at the intersection of workings to make timely management decisions and sustainable development.

2 Research methods

The study of rock mass management technologies uses a systematic approach that includes a set of studies: analytical studies based on literature data, field studies (surveying, stress and strain measurements), laboratory tests (modelling of materials) and theoretical (finite element method, thermodynamic, energy, etc.) [7-11].

Considering the uniqueness of each deposit, the priority is given by methods with experimental confirmation of calculated parameters. Applied technologies are divided into various types based on the use of the destroyed rocks residual bearing capacity. The range of studies in this area includes: "Structural analysis", "Structural dynamic", "Analytical and numerical methods for structural analysis", "Stability calculation".

In underground construction geological and surveying tools are used, including [12-20]:

- stress measurement in lining by strain gauges;
- deformation measurement in lining by levelling (fig. 1).

Fig. 1. Stress σ_x distribution diagram of the frame lining for measurements No. 1-5.

The dependences of stresses on time obtained by the authors are described mathematically in the course of analytical studies. The state of the rock masses during mining is monitored by a complex method, including analysis of analogues, calculations using theories of elasticity, plasticity, and transverse deformation, experimental studies using acoustic and electromagnetic emission, seismic sounding, ultrasonic and shock wave monitoring. The basis for successful field development is the combination of the tasks of ensuring geomechanical safety by introducing system monitoring and diagnosing the condition of the rock mass.

System monitoring of the geomechanical state of the ore-bearing massif and underground structures provides continuous monitoring and technical diagnostics. The primary monitoring is the separation of the geotechnical system in the control of individual objects with the synthesis of results to predict the effectiveness of the functioning of the production cycle of the system as a whole. It is a complex of theoretical concepts and a fleet of technical means for their implementation in practice and is carried out using sound metric, surveying, and optical instruments, string tensometers, deep and ground

benchmarks, electrical circuits, visual and indirect methods for changing the salinity of mine water. Establishing a relationship between natural and technological factors makes it possible to clarify the standards of discovered, prepared, and ready for excavation ore reserves under geomechanical conditions.

3 Results

The development of rock deposits increases stress to critical levels with a deterioration in the quality of subsoil use, which increases the urgency of the problem of geodynamic processes control. The maximum stresses develop during the stage-by-stage mining of deposits by chamber-pillar systems in the places of equipment of temporary and permanent pillars and in areas of changing the power of ore bodies.

The level of critical stress here exceeds the average values by 2-3 times. Reducing the level of stress to a safe value is ensured by engineering activities with advanced unloading of massifs. The optimum ratio of ore deflection parameters and stress levels is ensured by using technology optimization techniques based on account of seismic blasting effects on the array and surface objects.

A significant role in the behaviour of ore-massif in underground mining of complex structural deposits, for example, Vostok (Kazakhstan), is played by faults and macro fractures forming fracture and splitting zones of rocks with seams filled with friction clay or quartz-carbonate veins [21 - 28].

The physical and mechanical properties of the rocks obtained (by the authors) by the laboratory and field studies at the Vostok deposit (Northern Kazakhstan) are presented in Table 1.

Table 1. Physical and mechanical properties of rocks.

Characteristic of rocks	Density ρ , g/cm ³	Compressive strength σ_c , MPa	Tensile strength σ_t , MPa	Compressional velocity V_c , m/s	Acoustic impedance, 10 ⁵ g/s cm
Andesitic porphyrites	2.80	105.9	8.4	4753	13.4
Quartz porphyry modified	2.87	77.8	3.8	3452	9.9
Quartz porphyry sheared	2.71	26.4	3.4	2612	7.09
Facette conglomerate	2.73	77.0	14.5	-	-
Mineralized siltstone-argillite	2.70	62.0	15.0	-	-

The dynamic of stress changes closer to the ore body was investigated by the strain gauge method. The deformation of the lining was calculated by measuring the distances between the bench mounted on 27 metal frames on a 13 m long section. In the other development, 9 metal

frames were installed. The strain gauge station was placed on 5 metal frames in the second development. On each frame 9, measuring points were installed, including individual sensors glued on three planes. Stresses and strains were recorded once a month. According to the measured deformations ε_0 , ε_{f1} , ε_{f2} , the main deformations were calculated:

$$\varepsilon_{1,2} = \frac{\varepsilon_{f2} + \varepsilon_{f1}}{2} \pm \frac{\sqrt{2}}{2} \sqrt{(\varepsilon_{f2} - \varepsilon_{f1})^2 + (\varepsilon_0 - \varepsilon_{f1})^2}, \quad (1)$$

And angle φ between ξ_0 and ξ_1

$$tg\phi_0 = \frac{\varepsilon_{f1} - \varepsilon_{f2}}{2\varepsilon_0 - \varepsilon_{f1} - \varepsilon_{f2}} \cdot tg\phi_1, \quad (2)$$

The principal stresses, according to Hooke's law:

$$\sigma_1 = \frac{E}{1-\mu^2} (\varepsilon_1 + \nu\varepsilon_2), \quad (3)$$

$$\sigma_2 = \frac{E}{1-\mu^2} (\varepsilon_2 + \nu\varepsilon_1), \quad (4)$$

where E – elasticity modulus; ν – Poisson's ratio.

Normal stresses σ_z – vertical and σ_x – horizontal:

$$\sigma_z = \sigma_1 \sin\alpha - \sigma_2 \sin\alpha, \quad (5)$$

$$\sigma_x = \sigma_1 \sin\alpha - \sigma_2 \sin\alpha. \quad (6)$$

The looseness of the massif was determined based on the measurement results. The stress dynamic was measured by sensors of the well walls displacement drilled in the study area [29-32]. It is established that the well walls displacement is a function both of the load intensity and the time of its action (fig. 2).

According to the propagation of deformations, the massif is differentiated into phases:

- in the initial phase of deformation the lining increased from 2 to 16 mm;
- when cutting the ore body from the hanging side, the deformation of the lining increased to 19 mm;
- in the development phase of stopping the lining deformation developed until damage.

With the progress of excavation, the average deformations for 1, 2 and 3 months were: 43, 119, 128 mm correspondingly. The maximum deformations of the lining are noted in frames located close to the clearing face and in the area of the fault. So, after 6 months, the deformations in the upper arch of frame No. 4 were 233 mm, the width of the lining at a distance of 0.5 m from the rocks increased by 55 mm. Frame number 19 failed because the center of its upper arch was lowered by 432 mm, and the width of the locks increased by 312 mm.

The load on the lining of advance workings is connected with the phase of stopping correlatively. As long as the ore body behaves as a beam pinched in the sides, rock pressure is distributed evenly. After cutting the segments from the hanging side, the load on the lining elements from stopping increases (Table 2).

Displacements in the fracture zone (sensor No. 10) are caused by a strong disturbance of the fracture zone rocks with the deterioration of their physical and mechanical properties, which sharply reduces the stability of rocks in this zone. It has been established that pillars between cross

drift equally experience higher deformations than the rock masses even at equidistance from the stope influence (fig. 3).

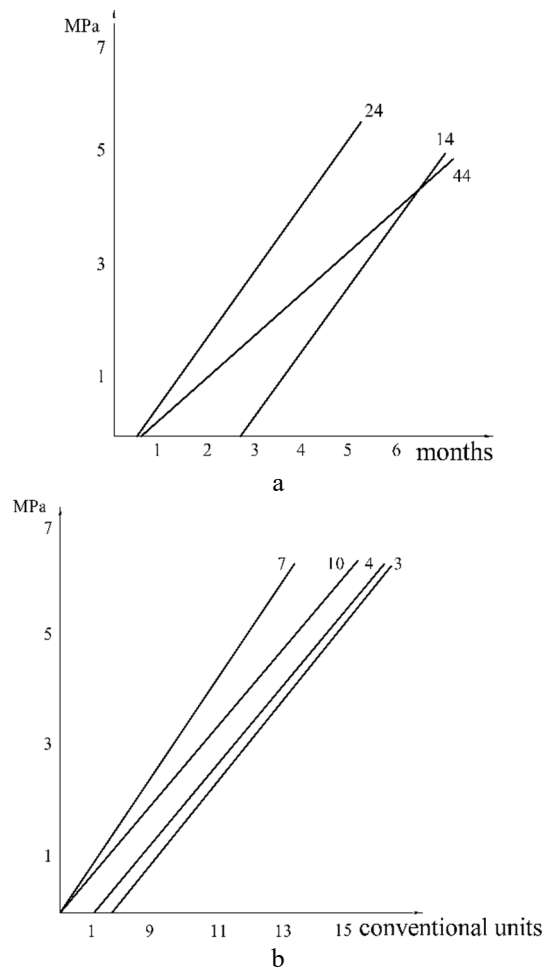

Fig. 2. Sensors indications: a – pressure, b – displacement.

Table 2. Results of stress and strain measurements of the sensors.

Time t , months	Deformations d , mm				Stresses σ , MPa		
	Sensor numbers				Sensor numbers		
	4	10	3	7	24	44	11
1	0.9	0.15	0.24	0.09	-	-	-
2	3.6	0.55	0.21	0.22	2.3	0.12	0.04
3	-	2.2	0.26	0.24	9.7	2.35	0.85
4	-	-	0.50	0.26	7.65	5.1	2.65
5	-	-	0.90	0.62	-	6.35	3.6
6	-	-	1.00	0.8	-	-	3.7

Three sections of operating stresses characterize the massif. A slight increase in stress characterizes the initial section. With the approach of the sewage treatment front and the increase subsurface mining area, the ore massif is experiencing an increasing load.

The ratio of rock load above the exploited space and in the stress concentration zone or the pillar presents the information about the massif geodynamics. During the actual mining over the area of length L and width I there is a load Q caused by the mass of overlying rocks (γH):

$$Q = L_1 \gamma H \quad (7)$$

Fig. 3. Well walls displacement in time for sensors No 3, 4, 7, 10.

The magnitude γH , in this case, is 98 MPa. If we allow that the mining effect extends to the same length l , then the load is:

$$Q = Q_1 + Q_2 \quad (8)$$

where Q_1 is the overlying caved rock load, Q_2 is the load caused by technology.

The load growth in the area of stress concentration in specific conditions is 15-20 % of the gravity component and 39 MPa that is less than the compressive strength of rocks - 54-75 MPa.

The monitoring of the rock mass state by the displacement sensors 3, 7 and pressure sensors shows a slight increase in strain and stress during the first three months of actual mining. Only after three months, the influence of cleaning works is seen. Rock mass stresses increase slower than in the ore. At the end of the actual mining, the stresses and strain in the massif stabilize.

When combining stopping and development headings, their allowable sizes depend on the roof rock behaviour. If structural blocks of rocks are shifted into the developed space, the roof takes the form of a vault. In this case, adding waste rocks worsens ore dilution and losses of metals in the ore dressing, that is why the aim is to save flat roof choosing the work options at which the rocks in the lower layer wedge and hold rock load inside the vault of natural balance (fig. 4).

Fig. 4. The condition for the formation of a flat roof: h – is the height of the arch of equilibrium; L – is the span width; d_1 – is the length of elementary structure; d_2 – is the height of structural units; γ – is the volume weight of rocks; q – is the

moment of force, A and B – are the edges of the arch of equilibrium.

Vetrov-Golik model describes this condition:

$$L_{max} = 2d_2 \sqrt{\frac{10R_{com}}{K_2 \gamma d_1}} \quad (9)$$

where L_{max} – the maximum span of the flat roof; d_1 – the horizontal size of structural blocks, m; d_2 – the vertical size of structural blocks, m; γ – volume weight of rocks; K_2 – safety factor.

If the roof is composed of rocks, deformations in which do not exceed the plastic limit, the allowable span of the flat roof is determined from the equations:

$$q = \frac{L_0 h_0}{3}; h_0 = \frac{L_0}{2V_0}; q = \frac{L_0}{2V_0}; M_q = \frac{L_0 \gamma}{18V_0}; T = \frac{10R_{com}}{R_c} \frac{1}{2} d_{oc};$$

$$M_T = T \frac{5}{2} d_{oc} = \frac{10R_{com} \cdot 5d_{oc}}{18K_2}; R_{com} = R'_{com} = R''_{com}.$$

The width of the flat span can be increased, fastening the structural rock blocks by anchors, concrete, etc.:

$$q_n = \frac{L_3 b \gamma}{2}; M_q = \frac{L_3^2 b \gamma}{8}; T = \frac{10R_{com}}{K_2} \cdot \frac{2dn_2}{3};$$

$$M_T = \frac{10R_{com} \cdot 10d^2 n_2}{18K_2}; L_3 = 298dn_2 \sqrt{\frac{10R_{com}}{K_2 \gamma b}}.$$

The efficiency of using rock structures in the operation of underground structures is achieved by improving the quality of mined ores and the safety conditions of workers [15-18]. The crushing of distinct rock blocks is a critical component of optimizing the technology for extinguishing the developed space, which makes it possible to develop deposits with an environmental and economic effect while ensuring the safety of mining operations.

In underground mining of rock ore deposits, the phenomenon is realized by constructing the boundaries of the area of dangerous displacements in the rock mass using geophysical research methods. Geophysical monitoring of field development processes allows us to assess the state of the system and the stress-strain state of the rocks, which allows us to assess the stability of the massif under various conditions of void formation.

The proposed approach can be used to detail working projects for managing the state of ore-bearing massifs of rock deposits of complex structure.

4 Conclusions

In the process of intensive intervention by mining operations, the ore-bearing massif the structural units of rocks are destroyed and come into contact with each other, often with the creation of jammed systems.

Under certain conditions, emerging structures are used to control the geomechanics of a given section of the earth's crust. The adequate nature of this phenomenon, which can be observed during ore production, allows predicting the behaviour of rock masses with sufficient detail to control the ore-bearing mass, which allows adjusting the development parameters to obtain the economic effect of improving the quality of mined ores

and reducing the risk for workers. The efficiency of using rock structures consists of saving labour and materials for controlling the state of rock masses during underground work.

In underground mining of ore deposits, the dynamic of stresses and strains at the intersection of stopping and development headings can be predicted with sufficient detail to control the ore-displacing massif, which makes it possible to adjust the development parameters with the economic effect of improving the quality of mined ores and reducing the risk for workers.

The novelty of the proposed method for predicting the dynamics of rock pressure is the use of mechano-structural properties of discrete structural rocks, in contrast to most methods based on the mechanics of a continuous medium, which brings the calculation results closer to the actual position of the massif.

Machine learning: technologies and potential application at mining companies

Snizhana Zelinska

Kryvyi Rih State Pedagogical University, 54 Gagarin Ave., Kryvyi Rih, 50086, Ukraine

Abstract. Implementation of machine learning systems is currently one of the most sought-after spheres of human activities at the interface of information technologies, mathematical analysis and statistics. Machine learning technologies are penetrating into our life through applied software created with the help of artificial intelligence algorithms. It is obvious that machine learning technologies will be developing fast and becoming part of the human information space both in our everyday life and in professional activities. However, building of machine learning systems requires great labour contribution of specialists in the sphere of artificial intelligence and the subject area where this technology is to be applied. The article considers technologies and potential application of machine learning at mining companies. The article describes basic methods of machine learning: unsupervised learning, action learning, semi-supervised machine learning. The criteria are singled out to assess machine learning: operation speed; assessment time; implemented model accuracy; ease of integration; flexible deployment within the subject area; ease of practical application; result visualization. The article describes practical application of machine learning technologies and considers the dispatch system at a mining enterprise (as exemplified by the dispatch system of the mining and transportation complex “Quarry” used to increase efficiency of operating management of enterprise performance; to increase reliability and agility of mining and transportation complex performance records and monitoring. There is also a list of equipment performance data that can be stored in the database and used as a basis for processing by machine learning algorithms and obtaining new knowledge. Application of machine learning technologies in the mining industry is a promising and necessary condition for increasing mining efficiency and ensuring environmental security. Selection of the optimal process flow sheet of mining operations, selection of the optimal complex of stripping and mining equipment, optimal planning of mining operations and mining equipment performance control are some of the tasks where machine learning technologies can be used. However, despite prospectivity of machine learning technologies, this trend still remains understudied and requires further research.

Topicality of the research consists in the fact that at present many mining companies are facing the necessity of increasing efficiency of their performance in conditions of rising competitiveness and market globalization. To achieve the set goals, it is essential to reduce costs, optimize use of equipment and human resources.

Mining companies often implement technological process control systems where a great amount of current information on their production processes is stored. This information is used directly for operating control and management. The practical value of the accumulated information in the long term mainly consists in statistical reporting.

In view of the above, a need arises to use the accumulated information for identifying segments of technological processes of less efficiency. To do this, means of machine learning technologies may be used.

Machine learning focuses on development of applications and specialized algorithms capable of self-learning and adapting. Application of machine learning

algorithms enables processing data to search for relevant patterns and change programme actions.

The article aims to study technologies and potential of machine learning at mining companies.

To reach the set research objective, the following *tasks* should be accomplished:

- to reveal the essence of machine learning;
- to describe machine learning algorithms;
- to provide an example of a subject area of machine learning application at mining companies.

Despite the tremendous development of machine learning technologies in the recent decade, artificial intelligence remains a rather ambiguous concept. It includes a number of subject areas: from generation of plausible images on a certain theme to prediction of time series. Methods of machine learning are the basis of artificial intelligence technologies but remain a highly tailored solution to every particular task.

Machine learning is a sub-division of artificial intelligence dealing with methods of elaborating algorithms capable of finding dependencies in data and

* Corresponding author: zvrit-zss@ukr.net

learning. Learning from examples is based on identification of patterns by individual empirical data. Deductive learning is implemented through formalization of expert knowledge and its transfer to the knowledge database [3].

S. A. Shumskiy suggests creating strong artificial intelligence using principles of the human brain work and does a review of the current state and prospects for further investigations into machine intelligence [12]. Only machine learning supported by the achieved level of computer capacities is able to make machine intelligence fast soar to the human level and engage these capacities into solving the problems only people can manage.

Methods of machine learning include: supervised learning, unsupervised learning, action learning, semi-supervised machine learning [11].

Supervised learning is implemented through inputting data into a machine and their preferable outputting, objects called “a teacher”. Its objective is to study the general rule which will enable displaying input data at output. Algorithms like that use everything they have learned earlier when dealing with any new data.

Many types of learning are based on the generalizing transition from training data to new data through studying similarities between them. In grouping models, which include, in particular, decision trees, such similarity takes on the form of equivalence relation, or object-space splitting: two objects are considered similar if they are in the same segment of splitting [10].

Unsupervised learning assumes that labels, tags or explanations are not transferred to the learning algorithm with respect to the input, and it remains as it is, for searching for a relevant structure in it. Such algorithms are used to find hidden patterns in data arrays and draw one’s own conclusions or conclusions from the data obtained from data sets.

In practice, learning is implemented through direct interaction with the changing environment and is to fulfil a certain task (e.g. operating a vehicle, equipment positioning) without informing whether it is reaching the destination or not.

Semi-supervised leaning means that the subject “teacher” gives the machine data with certain drawbacks, and results are not obtained.

Use of a particular method of machine learning is conditioned by the subject area of its practical application. The most preferable methods of machine learning are supervised learning, unsupervised learning that enable solution of most tasks of mass data processing.

Matrices, graphs, probability, function, gradient, minimum of function, optimization, error are the most popular objects of neuromathematics that are frequently used in machine learning.

The array of source data in a particular neural network is the most illustrative example of practical application of a matrix (a table of numbers) [5]. Fig. 1 presents the generalized chart of a single-layer perceptron that recognizes digits.

The perceptron consists of three types of elements, namely: incoming signals from sensors, associative elements and responders. Thus, perceptrons allow

creating a set of “associations” between incoming stimuli and the required output response.

Fig. 1. A single-layer perceptron.

In the modern terminology, perceptrons may be classified as artificial neural networks:

- with a single hidden layer;
- with a threshold transfer function;
- with direct signaling.

Another object, a graph, is a set of vertices and a corresponding set of connections between them. It is a good visual mathematical object depicting a model chart or an algorithm structure.

In mathematics, a graph is often represented by an ordered pair $G=(V, E)$, where V is a set of vertices, E is a set of edges linking these vertices.

The given diagram shows that the source image may be presented as a corresponding 7-by-5 matrix consisting of ones and zeros, Fig. 2.

$$\begin{pmatrix} 0 & 1 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 \end{pmatrix}$$

Fig. 2. A matrix of perceptron values.

Various calculations that can be performed on such a graph enable finding, for instance, the shortest bypass road or the nearest handling facilities, planning the optimal haulage route, etc.

Description of links between objects with the help of graphs is implemented through associating edges to certain quantitative values, qualitative attributes or required characteristics called weights. In the simplest case, this can be an edge sequence numbering showing the order of their direct consideration (priority or hierarchy of events).

The graph edge weight may depict:

- the haulage route length (transportation);
- bandwidth (communication);
- voltage or current strength (electric circuits);
- the conductor colour in the wiring diagram of an electronic device;

- the amount of work completed (production);
- link valences (chemical formulas), etc.

When assessing machine learning, the following requirements are considered: speed of operations; assessment time; implemented model accuracy; ease of integration; flexible deployment within the subject area; ease of use; result visualization.

Application of machine learning technologies in the mining industry is a promising and necessary condition for increasing mining efficiency and ensuring environmental security. However, despite prospectivity of machine learning technologies, this trend still remains understudied and is not yet implemented to the required extent.

According to M. B. Nosyrev, A. V. Druzhinin and N. B. Glushenko, increased efficiency of mining companies' performance depends on arrangement of coal mining by the open pit method. Unique machinery used here and sophisticated technologies require practical application of intelligent technologies and simulation of mathematical models when designing, planning and controlling the life cycle of a coal pit [6].

One of the solutions to these tasks consists in transferring the expert system technology into the artificial intelligence sphere of industrial information management systems. Traditional problem areas for expert systems are: identification and diagnostics used for situation interpretations; prediction used for determining probable sequences of the identified situations and states; planning for elaborating goals and adaptive control for achieving the set goals.

Here, application of machine learning technologies enables obtaining qualitatively new knowledge based on which the following tasks can be accomplished:

- selection of the optimal process flow sheet of mining operations;
- selection of the optimal (by basic characteristics) complex of stripping and mining equipment;
- optimal operational planning of mining operations and mining equipment performance control;
- useful minerals quality;
- life of mine;
- completeness and quality of useful mineral extraction and processing;
- mine field sizes;
- the designed depth of open pit and underground operations;
- pmining elements sizes (level height, sizes of blocks, panels, rooms);
- the period of construction and exploitation of the designed deposit thickness.

The above classification shows that current formal prediction and control models in mining cannot always be adequately applicable at a mining enterprise and cause the necessity of developing new approaches to creating systems on the basis of machine learning technologies.

For instance, V. N. Soloviev et al. investigates methods and algorithms used at solving problems of assessment, regression and filtration, image recognition and clusterization [8]. The considered classic and modern implementations of machine learning algorithms can be

applied to solving tasks of processing data of a particular subject area.

A. O. Zibert and V. V. Miroshnichenko set the task of applying machine learning algorithms to increase efficiency of truck performance. They provide description and give an example of practical application of the perceptron model to predicting performance periods without maintenance-caused outages based on the classification of such performance periods [4].

The authors also provide detailed description of training data and the method of generating these data from the database, consider the results of the perceptron model application and conclude on possible application of the used model to solve machine learning tasks.

The intellectual mining-engineering system should continuously identify and monitor characteristics of a controlled object. Feedback and availability of a reliable automated control system are also required. Such systems are always controlled under conditions of principal uncertainty of development and incomplete observability. Building formal models for most processes of a mining company is extremely complicated.

In view of the above, it is necessary to implement machine learning systems at mining companies considering interaction of various production components including engineering, technological and socio-engineering mining objects.

According to I. O. Temkin and A. N. Goncharenko, there currently exist many intellectual models, methods and technologies widely used in controlling complex industrial objects and socio-engineering systems: data mining; fuzzy logic; probabilistic prediction models; neural network models of situation recognition; genetic algorithms; knowledge acquisition; natural language processing; search for solutions in conditions of insufficient information provision [9].

Another problem that can be solved with the help of machine learning is engineering research during building of complex engineering systems (F. N. Abu-Abed [1, 2]). Timely recognition of pre-emergency situations that can occur during operations may provide production stability and safety. A pre-emergency situation is an emerging process different from the regular one and requiring a prompt response. The largest problems in timely detection and identification of pre-emergency situations occur in a complex engineering system during its building.

Examples of complex engineering plants include drilling rigs for oil and gas wells drilling, radars and other complex engineering systems. Complications are caused by:

- the necessity of operational visual control over current technological processes in the system;
- the necessity of making relevant decisions and subsequent production of recommendations in the real-time mode in conditions of insufficient information;
- the necessity of operational accounting of a large quantity of initial data and diverse factors;
- insufficient qualification of some enterprise employees [1; 2].

In recognizing pre-emergency situations occurring during the trial operation of systems, the number of attribute space dimensions is rather big and boundaries

between pre-emergency situation classes are blurred. Application of cluster analysis and Bayesian classification to solving the task of pre-emergency situations recognition during well drilling is not reasonable. With this purpose, artificial feedforward neural networks capable of being taught through practical use of the back

propagation algorithm may be used as a mathematical tool for solving the pre-emergency situations recognition task.

Many mining companies apply dispatch systems and machinery monitoring. The automatic system of controlling mining and transportation complex “Quarry” of VIST Group is an example of such a system [7]. Fig. 3 presents the system architecture.

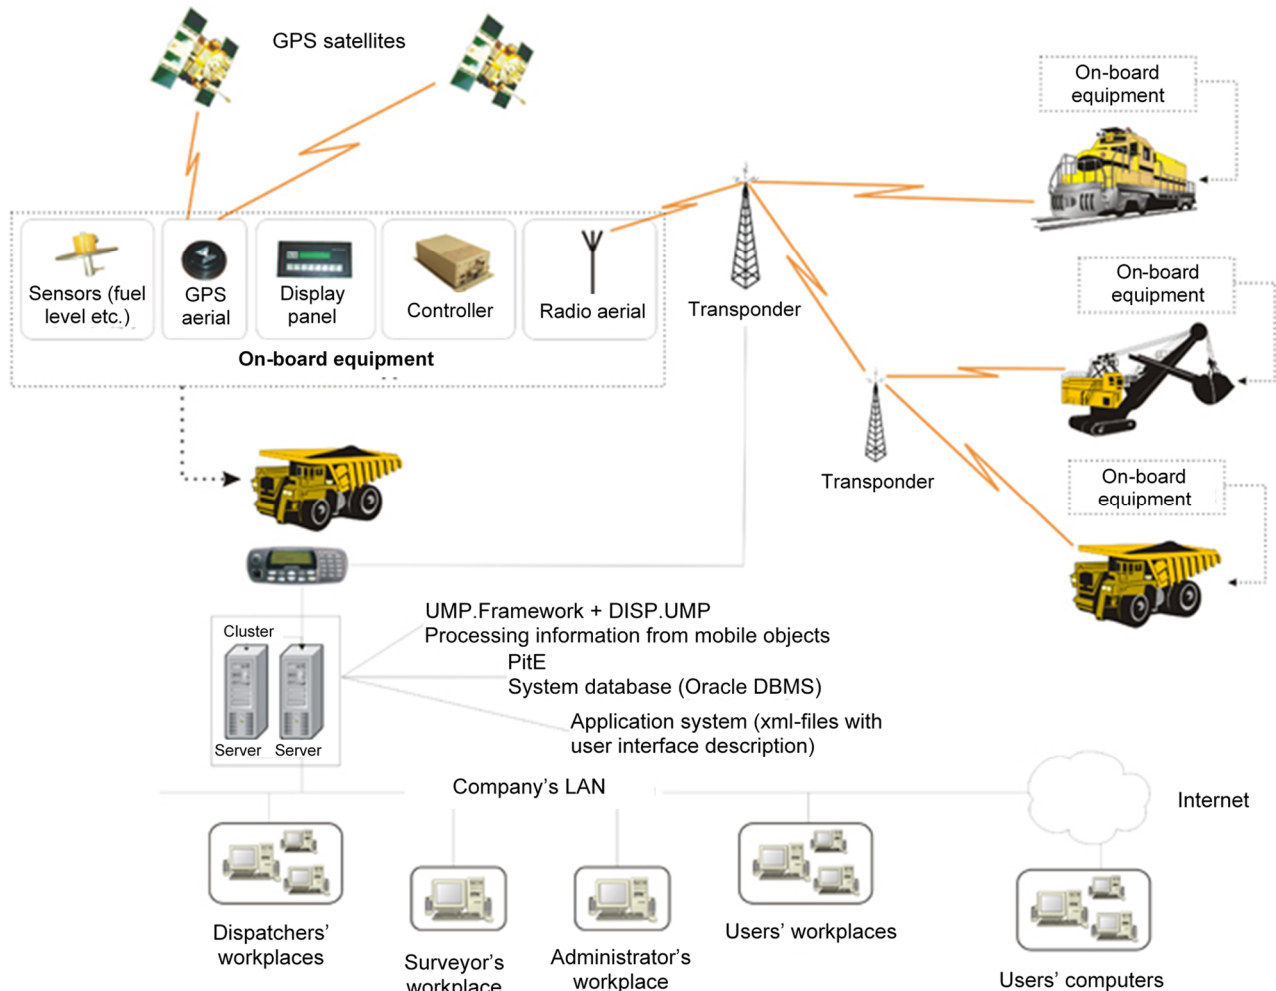

Fig. 3. Architecture of the automatic system “Quarry”.

The automatic system “Quarry” receives data from the following sensors:

- sensors of machinery position, speed and route (GPS);
- handled ore mass weight sensors;
- excavator bucket position sensors;
- pressure sensors in the bulldozer turbine;
- truck wheel pressure sensors;
- excavator operation currents sensors;
- fuel level sensors.

The information users are:

- the dispatcher control room of an enterprise, various users of the enterprise local network;
- other engineering services of an enterprise – statistics on real equipment performance, stand-by time, kilometers travelled, handled material volumes.

Besides, it is possible to detect equipment stand-by time or determine periods of its most efficient

performance on the basis of the collected information.

However, due to a great amount of the information processed, analysis of historical data is rather labour consuming. To eliminate the problem, various data processing algorithms should be used to enable prompt analysis of causes of inefficient equipment use and search for ways of reducing the number of and preventing such situations.

As the initial data for the set goal of increasing efficiency of mining equipment use are rather similar to the presented examples of machine learning use, one may say about use of machine learning algorithms for determining the optimal mode of mining equipment performance based on dispatch system data as well as determining factors impacting efficiency of mining equipment use.

To estimate the above assumption, one can use the perceptron-based algorithms of machine learning through

comparing the obtained predictions with the real data. The perceptron consists of three types of elements: signals from sensors, associative elements and responders. Thus, perceptrons enable creation of a set of “associations” between the incoming stimuli and the required output response.

The perceptron performance may aim at creating the following classification of mining equipment:

- class 1 – probability of mining equipment stand-by caused by possible maintenance within the following 30 days makes 100%;

- class 2 – probability of mining equipment stand-by caused by possible maintenance within the following 60 days makes 100%;

- class 3 – probability of mining equipment stand-by caused by possible maintenance within the following 90 days makes 100%;

- class 4 – probability of mining equipment stand-by caused by possible maintenance within the following 120 days makes 100%;

- class 5 – probability of mining equipment stand-by caused by possible maintenance within the following 150 days makes 100%;

- class 6 – probability of mining equipment stand-by caused by possible maintenance within the following 180 days makes 100%.

The following information on mining equipment stored in the dispatch system database may be input into the perceptron model:

- average rate of mining equipment performance (km/h) per shift;

- average energy consumption per shift;

- average inclinometer reading value (degrees) per shift;

- average temperature (degrees centigrade) per shift.

However, mining production possesses a number of specific features that condition complexity of implementation of formal methods and models of control.

The first and the most significant feature of a mining company is production which is discrete-continuous in character. The second but not less important feature is a specific controlled object – nature (parameter distributability, process stochasticity, etc.). Another feature is specificity of the control system which includes complex functional blocks, such as survey, geological, etc.

Thus, based on the obtained results, the following conclusion can be drawn: it is possible to apply machine learning algorithms to enhancing efficiency (in the medium term at least).

Besides, further investigations are required, in particular into application of other machine learning algorithms and enhancement of initial data for obtaining better results of an algorithm operation. Another direction of research is application of machine learning technologies to prediction of not only stand-by periods but also efficiency of a mining equipment unit in the short, medium and long term, etc.

Abstract. In this work complex investigations of the abrasing wear of lining of self-grinding mills (semi-autogenous grinding mills) are carried out with the obtaining of mathematical models of wear-abrasing of elevators in terms of height, weight, volume and worn-out area. In particular, according to the location and nature of the abrasing wear processes, the liner-lifters mill self-grinding are identified in three typical groups. During 1 year, in the conditions of Ingulets GOK, the monitoring of the abrasing wear of selected groups of lifters of self-grinding mills was performed. On the basis of the experimental data calculationed in the Microsoft Office Excel program, a set of mathematical models of lifter abrasing wear was obtained in terms of height, weight, volume and worn-out area. The obtained dependencies are recommended for prediction of abrasing wear of lining and necessary frequency of replacement of inserts-lifters. In addition, the research of wear of lining made of cast iron RF-4, showed a significant reduction in their abrasing wear compared with steel 110G13L. Thus, it has been shown that the selection of liner-lifters materials can reduce the inter-repair period by 3 times or more (replacement of worn-out lifters). A comparison of the actual picture of the abrasing wear of elevators and Simulation Statics simulated result (using SolidWorks) stresses shows the convergence of the arrangement of the zones of maximum stresses and the maximum abrasing wear of the lining. Investigation of the influence of the stressed state of lining plates on the intensity of their abrasing wear – a promising direction for further research.

1 Introduction

The process of destruction (grinding and crushing) of mineral raw materials is the most energy-intensive and labor-intensive technological operation of ore dressing [1–3]. Investigation of the energy intensity of the processes of ore preparation, including the disintegration of ore, which was carried out in Eastern Europe in 14 mining ore dressing plants that process different raw material physical and mechanical properties, show that 50–70% of the total ore disintegration process accounts for 50–70% expenses, while the electric power consumption for grinding is on average about 60%, and for crushing only 5% [4–6]. It actualizes the research of equipment and technology of milling minerals.

From the end of the twentieth century semi-autogenous grinding (SAG) of ores is the most progressive technology of ore preparation in world practice. As of 2010, in the world mining industry, about 200 large mills of full or partial SAG were in operation,

including about 100 of them working in the iron ore industry, 30 in copper, while others – in dressing ore of rare and noble metals. In comparison with grinding in rod and ball mills SAG is characterized by a number of advantages:

- stages of middle and small grinding are excluded;
- saving of crushing bodies (balls and rods are not used);
- there is no contamination of the crushed material with metal;
- improvement of technological indicators of further dressing due to better disclosure and less sludge formation;
- in the processing of gold-bearing ores followed by cyanide losses of gold with iron scrap and crumbs are eliminated, the consumption of cyanide is reduced and the working conditions on quartz and silicone-sensitive ores are improved;
- when flotation of molybdenum ores, the use of SAG (self-grinding) mills improves the dressing rates associated with less "molten" scaling of molybdenite [1, 5–8].

* Corresponding author: ukcdb@i.ua

The critical nodes of semi-self-grinding mills from a techno-economic point of view are drum lining, bearings, washing drum, gear gears of power drives (Figure 1), which account for 70–90% of operating costs [5].

Fig. 1. The mill is a wet type of self-grinding type “Cascade”, a general view: 1 – drum; 2 – lifts; 3, 8 – face caps; 4 – boot pin; 5, 11 – bearings; 6 – boot device; 7 – grating; 9 – washing drum; 10 – crown gear; 12 – unloading pin.

Of these, more than 50% – the proportion of lining (its cost, the cost of installation work, planned idle time). Therefore, durability and reliability of lining is a topical scientific and technical problem.

The process of abrasing the lining is determined by the energy of mechanical influence on it from the ore, the strong characteristics of the lining itself and milling ore. Proceeding from this, the following factors significantly affect the abrasing wear of the lining:

- the size of the lumps of the original material;
- maximum mass of ore lumps;
- durability and wear resistance of lining material;
- height of fall of ore lumps (pieces);
- sliding of the rock mass on the lining, which is determined by its profile;
- degree of filling of the drum mill and its frequency of rotation;
- properties of ore: strength, abrasiveness, and in the case of wet grinding – also the density of the pulp.

The lifts in the mills play two important functions – first, it is protection against the wear of the mill shell. Secondly, it is ensured that the ore is raised, when they rotate the drum, they capture pieces of ore, lift them to a certain height, falling from which the ore is self-milling. Therefore, the efficiency of the process of SAG ore in the mills depends to a large extent on the design, location and serviceability of lifters.

2 Literature review

Many researchers have investigated the processes of abrasing wear of the lining of the semi-autogenous grinding mills and the impact of wear-abrasing on the technical parameters of the milling process. In work [9] the effect of lining liners wear on the productivity of the mill was studied. An analysis of fully worn and new inserts-lifters was conducted, as it was in line with the

major changes in the mill’s operating conditions. It has been found that worn-out mills are more prone to obtaining fine classes, possibly due to the reduction of strong collisions with high impact energy. When abrasing lining material is ground mainly in cascade mode, and with the new lining – in the waterfall mode. Consequently, the wear of inserts-lifts affects the mill operation. Cascade mode (worn out elevators) causes an increased throughput of the mill at lower power.

In [10], the demolition of liners made from martensitic Cr–Mo steel was investigated. It has been shown that the replacement the WS–7HM (400 Brinell hardness) material on WS–222 (Brinell 500) material resulted in a 61% lengthening lifespan lifespan, a 38% reduction in the consumption of liner and a 7% overall material. In addition, the heterogeneity of the wear of the liners was discovered and their rational form was proposed, which takes into account the location in the working space of the mill.

In the paper [11], based on experimental studies and long-term observations, a quantitative assessment of the impact of wear on the liner-lifters on the milling performance itself was made. At the investigated mill there was an increase in the throughput of 10.5% over the life of the elevator. Separate effects of wear of the lift have also been isolated. It is established that increasing the throughput due to the wear of the liner can be further divided into the following components:

- an increase in the lattice diaphragm, 5.3%;
- an increase in the diameter of the mill, 3.2%, and
- a change in the profile of the insert, 2.0%.

D. Royston summing up the experience of Royston Process Technology Pty Ltd. and others. indicates that, taking into account studies of lifts of mills, self-milling for deterioration for their manufacture, the following main materials are used: heat-treated chromium–molybdenum (Cr–Mo) alloyed steel (hardness about 350 Brinell), bimetallic inserts using an “white iron” insert that can provide increased wear and tear in places prone to abrasion (end lining). In addition, polymeric rubber products that provide structural stability can be used as inserts [12].

In work [13] a modification of the form of an insert-lifter SAG was performed based on the 3D measurement of the wear profile of the insert. Experimentally, with the help of a specially designed measuring device it was established that the wear profile is not homogeneous. When finding the appropriate models that accurately described the wear rate of the liners, in order to achieve an even profile of the liner when removing the elevator, new designs of the liners were proposed. This not only increased the lifetime of the elevator, but also reduced the content of scrap metal. Application of the proposed method in the SAG mill 9.75×4.88 m showed that the wear profile of the insert along its length was uneven and the highest wear was between 1.25 m and 2.75 m in length of the shell of the mill. The proposed liners, unlike the standard type, did not have a uniform shape, and the height of the liners increased from 152 mm to 187 mm in the area where the wear rate was high. It is established that this new profile comes to a uniform profile at the time of insertion change. Such a technical decision has reduced

the amount of scrap to 30% of the current value of 47%, and on average lifetime of the liner will increase by 1500 h.

A similar approach to the retention of rational form of lining is also used in work [14]. Forecasting the evolution of the shape of the liner and changing performance during the lifecycle lifter allowed to offer a rational form of lifters. Forecasting of the dynamics of wear of elevator is done by the method of discrete elements (DEM). An analysis of the life cycle of the insert has shown a 20% reduction in power consumption, since increasing the volume of the SAG working chamber and blurring the profile of the lifts leads to less efficient mill operation.

At the same time, now is a lack of real comprehensive research on the wear of lining of SAG mills with the simulation of wear and abrading of elevators in terms of height, weight, volume and worn-out area.

3 Research objective and tasks

The purpose of this article is a comprehensive research on the wear-abrading of lining mills of the same milling with the obtaining of mathematical models of wear-abrading of elevators in height, weight, volume and worn out area. To achieve this goal, the following research objectives are formulated:

- in the actual conditions of the Ingulets GOK to monitor the wear-abrading of lifters of mills for self-grinding. According to the results of the monitoring, identify the typical groups of lifts-lifters;
- on the basis of the experimental data calculation in the Microsoft Office Excel, to obtain a set of mathematical models of lining of the elevators in terms of height, weight, volume and worn-out area;
- to analyze the wear of lifters made of steel 110G13L and cast iron RF-4;
- using the SolidWorks software simulation statics module to investigate the mechanical stresses in the work area of the lifters and compare the data with the actual picture of data of their wear.

4 Basic stages and research results

In the conditions of the preparation plant Ingulets GOK preparation plant (Kryvyi Rih iron ore basin, Ukraine), the nature and patterns of abrading wear of MMS-70-23 mills were investigated. In this case, elevators made of 110G13L steel, by location, were divided into three groups (Figure 2):

- I. Lifts No. 2 and 3, located on the end wall of the loading;
- II Lifts No. 5, located on the shell;
- III Lifts No. 7 and 8, located on the end wall of the unloading.

In addition, on a pilot sample mill MMS-90-30 the durability of lifters from cast iron RF-4 and SS alloy was investigated.

In researches in work the experimental researches of wearing of lining of mills of self-grinding in industrial conditions of mining complexes of Kryvyi Rih basin which generally lasted for more than 1 year were used.

The experimental data processing is done in the Microsoft Office Excel resource with the obtaining of mathematical models of polynomials and abrading wear curves of elevators in height, mass and volume abrading wear of elevators from the amount of processed ore and depending on the duration of their operation.

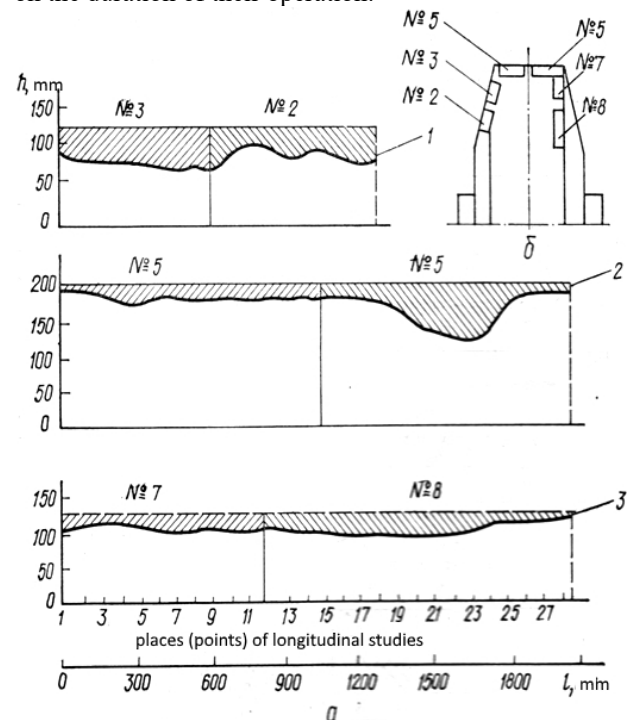

Fig. 2. Wear of lifters of mills MMS-70-23 at height h of a working surface (a) and a scheme of their location in a drum (δ). l – the metric size of elevators.

4.1 The first stage of research

The wear of lifters was measured at intervals of 1–1,5 months. The height of their working part and (h , mm) and volume (V , cm^3) was measured. In this case, the period of work of lifters and the volume of processed miner's mass were recorded. Elevators were measured at several points (Figure 2). The last measurement was carried out after processing 200 thousand tons of ore.

Let's analyze the results. As you can see from Fig. 2a, lifters number 2 and 3 wear out basically evenly. The maximum wear is observed at the junction – here the height of their working part decreases from 125 to 75 mm.

Lifts No. 5 wear out very unevenly. The greatest deterioration is observed on the elevators located on the side of the discharge – here they wear about half their height. The fact is that in the drum mill near the discharge grid there is an increased circulation of crushed rock mass, which also causes the heavy wear of these elevators before the unloading lattice.

The wear of lifters number 7 and 8 is uniform throughout their length, maximum wear in height – 30–35 mm.

4.2 The second stage of research

For an in-depth study of the wear of elevators of selected

groups I–III, their height was determined depending on the amount of processed mass. According to experimental data analyze in the Microsoft Office Excel, curves of wear and tear of elevators and mathematical polynomial models are obtained in height from the amount of processed ore of Figure 3.

Fig. 3. Dependence of lifters wear in height H (mm) on the amount of processed ore G (ths. tons). 1 – lifts No. 1 and 3; 2 – lifts No. 5; 3 – lifts No. 7 and 8.

The analysis of the obtained data shows that lifters No. 1 and 3 on the part of loading and No.7 and 8 on the part of unloading in height wear out with the same intensity before the processing of the first 120 thousand tons of ore. After that, the intensity of wear of lifters number 1 and 3 increases and after processing 200 thousand tons of ore their average height is almost 20 mm less than the height of lifters number 7 and 8. This, obviously, can be explained by the result of the action on the lifters by loading more large and abrasive lumps of ore than by unloading.

As measurements show, lifters number 5 wear out more intensively and after processing 200 thousand tons of ore, the average height of their working part decreases from 195 to 140 mm.

4.3 Third stage of research

Investigated the massive and volumetric wear of elevators. The results are shown in Figure 4 – dependence of mass and volume wear of lifters on the amount of ore processed G , ths. tons (and corresponding polynomial mathematical models).

The analysis of the obtained model curves shows that lifts number 5, 7 and 8 throughout the life of the service are worn evenly and after processing 200 thousand tons of ore their wear reaches 140 and 120 kg, respectively.

Lifts No. 1, 2, and 3 are worn less intensively before the processing of 100 thousand tons of ore, after which the intensity of their wear increases sharply and reaches 105 kg by the end of its lifetime.

4.4 Fourth research phase

The dynamics of the expansion of the conditioned wearing lining area S_{sn} was investigated, depending on the

amount of ore processed G , ths. tons.

Fig. 4. Dependence of mass (kg) and volumetric (cm^3) wear of lifters on the amount of processed ore G , ths. tons. 1 – lifts No. 1 and 3; 2 – lifts No. 5; 3 – lifts No. 7 and 8.

For this purpose, the amount of wear was divided into a height of wear for a particular elevator. For example, for elevator No.5 (S_{sn5}) using the corresponding polynomial models we find:

$$S_{sn5} = \frac{-0,0001x^3 + 0,0506x^2 + 2,8976x - 5,4119}{-0,0009x^2 - 0,099x + 196,78}$$

After calculations, we obtain the dependence S_{sn5} (cm^2) given in Figure 5.

Fig. 5. Growth of the conditional worn-out area S_{sn} (cm^2), lining depending on the amount of ore processed G , ths. tons.

As you can see, the expansion of the conditional worn-out area of the S_{sn} lining is linear and directly proportional to the volume of crushed ore.

4.5 Fifth stage of research

On a pilot sample mill MMS-90-30 also conducted researches of wear of elements of lining, made of cast iron RF-4. To characterize the wear of the lining, mass deterioration of all its elements was determined (Table 1).

From the analysis of the data obtained, it can be seen that the lifters made of cast iron RF-4, for 5 months of

work, were worn only 15 mm and were suitable for further operation. During this time, serial lifters from the 110G13L alloy were worn by an average of 55 mm in height and were partially replaced by new ones. From the SS alloy were manufactured and tested lifts 2 and 3. Lifts 3 for wear resistance were the same as serial lifts from steel 110G13L. The durability of lifters 2 from the SS alloy was significantly higher: after 5 months of operation, their average height was 110 mm, while the height of serial lifters decreased to 80 mm.

Table 1. Results of research of wear of lining of mill MMS-90-30.

Lining	Num-ber	Total mass, kg	Mass of worn part, kg	Relati-ve we-ar, mass, %	Pro-cessing of ore, tons	Specific costs of mass li-ning, kg
Lining of the loading end wall	98	37159	3255	8,76	379,3	8,587

Fig. 6. Parametric field of strength of the drum mill self-grinding at idling speed. Trapezoidal drum wall with bases: upper – 70 mm, bottom – 200 mm: a – isometric projection of the drum; b–the drum's side (profile).

The nature of the wear of elevator lifters in height is the same as the elevators of the mill MMS-70-23.

Experience has shown that lining, made of wear-resistant cast iron RF-4, is more durable than lining steel 110G13L. Lifts, made of cast iron RF-4, especially lift loaders, are more fragile and after 3-4 months. Operation is broken up by large pieces of ore, which is fed into a mill. Broken and torn elevators during rotation of the drum break other elements of the lining, which leads to the need for premature stopping of the mill for re-fusion. The following lines of service of separate groups of lining of mills MMS-90-30 are established: the armor of the loading end wall - 5 - 7 months; load lifters - up to 5; armor and lifts of luggage - up to 4; lattices - up to 4; sublattice lining - 7-8 months. Thus, the service life of individual elements of the lining of mills MMC-90-30 is relatively low and, most importantly, is unplanned, which makes it difficult to establish optimal inter-repair periods. In addition, the lack of service life of individual elements of the lining leads to the fact that when replacing a number of extremely worn items must be replaced and those elements whose wear is insignificant and they could work for a long period.

A significant disadvantage of the lining of mills MMC-90-30, which negatively affects the term of their service, there is also low reliability of nodes fixing elevators and lattices. As a result, there were cases of a breakdown of relatively few worn elevators and the loss of grate, which as a result of the dynamic impact in the process of the mill on other elements of lining removed them from the system. Therefore, in order to increase the efficiency, wear resistance and durability of the lining of serial mills MMS-90-30, it is necessary to apply high-strength materials and constructive improvement of all elements of lining, especially the nodes of fastening of elevators and lattices.

4.6 The sixth phase of the research

At this stage, using the SolidWorks software simulation statics module, mechanical stresses in the area of the shell were investigated. The obtained models in the idle mode mill mill itself (Figure 6) show an abnormally high mechanical tension in the vicinity of the vertical axis of the drum. For the loaded (nominal) operating mode of the mill itself, the grinding by the rule of superposition should be expected to increase the voltage in this zone - as the voltage at idle and the load factor will be added.

Reception of the epic of the stress of the elements of the drum mill self-crushing at different loads of the mill in the ore is an independent task and is planned by us in the subsequent studies.

At the same time, it should be emphasized the convergence of the data of simulation of mechanical stresses in the zone of the shell (Figure 6) and the real one, - experimentally established, - pictures of wear of the lining of mill MMS-90-30A (Figure 7).

5 Conclusions

1. According to the location and nature of the wear

processes, inserts-lifts appropriate to be divided into the following groups: I. Lifts, located on the end wall of the load; II Lifts, located on the shell; III Lifts, located on the end wall on the side of unloading. Monitoring of wear of lifters of semi-autogenous grinding mills was executed in conditions of Ingulets GOK within 1 year.

Fig. 7. The demolition of elements of lining of mills MMS-90-30A was experimentally established. 1,2 - lining and lifters of the loading end wall; 3, 4 - lining and lifts of the drum shell; 5, 6 - gratings and lifters of the zone of unloading; No. 3, 5, 6 - the numbers of lining and lifts of the lining.

2. On the basis of the experimental data regression received in the Microsoft Office Excel, a set of mathematical models of lifters' wear was obtained in terms of height, weight, volume and worn-out area.

3. From the analysis of the obtained data it is seen that the lifters made of cast iron RF-4, for 5 months of work, were worn only 15 mm and were suitable for further operation; During this time, serial lifters from the 110G13L alloy were worn by an average of 55 mm in height and were partially replaced by new ones. Thus, the selection of lift materials can be reduced by 3 times the inter-repair period (replacement of worn lifts).

4. Comparison of the real picture of wear of elevators and simulated using the simulation statics module SolidWorks stresses shows the convergence of the arrangement of zones of maximum stresses and maximum wear of the lining.

The authors thank the management of the Ingulets GOK's ore dressing plant, the Mekhanobrkhormet Research Institute for its assistance in conducting research.

Abstract. In the process of energy reform, liberalization and deregulation of the electricity market, a number of features have been identified that are related to the fact that in the conditions of market relations, the economic benefit and the price of electricity for consumers become a priority. There is certain isolation of networks and power lines from generation facilities; attention is lost to such an important problem as the reliability and safety of power supply. In this situation, the load on the power elements of the electric network increases, there is a need to create appropriate reserves of generating capacities, to increase the throughput of electric networks. All this involves increasing the role of system operators and improving supervisory control systems. The strategic goal of this study was to analyze the development of the electric power complex by the creation of smart grid systems as a platform for market, managerial and technological innovations that provide a transition to a new level of development of the electric power industry in Uzbekistan.

1 Introduction

In the last decade, the Smart Grid concept, which means an intelligent power system, has been actively discussed and developed abroad. In the USA and the European Union, it is considered as a technological concept of the electric power industry of the future [1-3] and it is, in fact, the state policy for the technological development of the electric power industry of the future.

There are various points of view on the concept of intelligent networks [4]. This explains the fact that, despite the relative similarity of the main factors in the development of intelligent networks in different parts of the world, the priorities are different. For example, in the EU, the priorities are the problems of integrating renewable energy sources, energy efficiency, as well as integrating the EU markets within the framework of a carbon-free economy, while for the United States, such problems as disruption of energy supply, situations of peak power consumption and aging of production facilities are priority. In China, the rapid development of the energy system, the need to unite large wind farms in the northern regions and create links between different provinces is the most urgent priorities.

The most general and technically complete definition of the concept of Smart Grid was formulated by scientists from the Institute of Electrotechnic and

Electronic Engineers (IEEE). So, according to their definition,

Smart Grid is a fully integrated self-regulating and self-renewing electric power system with a network topology that includes all generation sources, trunk and distribution networks and all types of electricity consumers, which are controlled using a single network of information and control devices and real-time systems. In fact, an intelligent electric network unites not one, but two networks – an electric and information-control network, which closely interact with each other and function simultaneously. Moreover, the management and control of each device of the electric network are carried out using the necessary “intelligent” devices, combined into a single information-control network.

Despite the existence of a number of definitions of the concept of intelligent energy systems, they can be generalized by defining an intelligent energy system as a combination of energy infrastructure and embedded / distributed information and communication technologies (software, automation, information processing). The combination of two infrastructures provides the necessary “intelligence”. This intelligence can be represented at different levels of the network (generation, network software, consumption, monitoring and control). Three basic principles of Smart Grid can be distinguished: security, standardization, integration.

* Corresponding author: obidtursunov@gmail.com

The reasons for the transition to Smart Grid are as follows: reduced predictability of demand behavior; the emergence of consumer generating ability and the need to return electricity back to the network; low energy efficiency and environmental friendliness of a grid built on analogous principles and technologies; digitalization of management of individual network elements and the risk of reducing their ability to mutual integration; the problem of the stability of hierarchical energy systems.

The main competitive advantages of smart grid technologies are: local measurement and monitoring; remote measurements and control; multi-information measurements and monitoring; controlled measurements and monitoring; general improvement in the quality of electric energy; low operating costs; minimization of expensive visual inspections of the system; automatic recording of time and operating parameters of specific equipment for timely preventive repairs; reduction of electric energy losses, improvement of environmental conditions, minimization of light and noise pollution; the best level of reliability and security; quick response to changes in external conditions; quick and easy access to the system database. The development of Smart Grid technologies also means a fundamental reorganization of the market for electric energy services [1, 2, 5-8].

Already today, the world has developed the understanding that a quick transition to the ideal Smart Grid model is impossible. In this regard, three generations of Smart Grid have been singled out, which make it possible to gradually move towards the target model: Smart Grid 1.0 – state of the electric power infrastructure, in which individual devices and system objects can be connected to the network without using common digital standards; Smart Grid 2.0 – the state of the electricity infrastructure, in which the connection of any system nodes is possible only if it is switched to a single IP protocol and included in a single integrated IP network; Smart Grid 3.0 is a flexible energy system that is based on the principles of decentralized management and equal rights for consumers and suppliers.

Hence, this study aims to present possible list of stages of the concept for creating smart grids in Uzbekistan by analysing the development of the electric power complex via creation of smart grid systems as a platform for market, managerial and technological innovations that provide a transition to a new level of development of the electric power industry.

2 Construction features and components of intelligent control systems

Today, the complexity of managing the electric power system is so high that fully centralized management becomes ineffective due to the presence of huge flows of information, when too much time is spent on transferring it to the center and making decisions [4, 6, 8, 9, 10, 11-13]. Control systems include a number of subsystems with different functional characteristics and interacting with various specialists, remote from each other. Therefore, some elements of organizational management

should be transferred from the center to the periphery with a clear delineation of rights and information access. The management system of the UES of the upper level should be a coordinating information management system that operates on the basis of appropriate standardized protocols and interaction interfaces.

The construction of a traditional control system of the unified electric power system (UEPS) is carried out according to the hierarchical principle with allocation of zones of responsibility for managing a certain level of the hierarchy [11-13].

A calculated union of groups of nodes that have “strong” connections with each other into one “equivalent” node with a total generation and consumption in this node takes place at the highest levels of the control hierarchy, and control is carried out by “weak” connections between these nodes for the output of parameters characterizing their work outside of normal mode. For each of the control levels, the processes of normal functioning are determined when disturbances in control node do not lead to an imbalance between consumption and production, and also do not cause disturbances in the connections operation between the nodes. In this case, the control carries out the process of transition from one stationary state to another, optimizing the current processes (modes) of the power system.

Power system objects are owned by various organizational structures with various commercial interests; therefore, when organizing the management process of such a complex object, it is necessary to take into account the market nature of relations between them, solving problems of resolving a conflict of interest. Therefore, commercial agents also function at each level. The infrastructural limitations associated with the insufficient bandwidth of many communications dictate the need to divide the common electric power system into electric power segments of UEPS.

Reliability issues in modern power grids are becoming increasingly problematic. The factors that determine the occurrence of these problems [9-13]:

- increased network congestion due to uncertainty, diversity and distribution of energy supply, taking into account environmental concerns and sustainable development; real-time electricity flows can significantly differ from those imposed during design or on-line analysis;
- increase in the number of powerful power lines over long distances contributes to the growth of instability and reduce the margin of safety; this phenomenon is reinforced by energy markets;
- the network is managed from one “end” from various locations and often taking into account the “lack” of investments and the restriction of land allocation; increase in energy consumption and peak demand creating a “conflict” with limited transmission capabilities; infrastructure aging; maximization of asset utilization thanks to modern technologies for monitoring, analysis and regulation;
- a consolidation of operator companies contributes to an increase in “area (covered by networks)” with more complex problems and requires more accurate

information and shorter time to make decisions; this problem is exacerbated by a lack of qualified personnel due to aging staff.

Under ideal conditions of demand management, energy storage and electric vehicles will be closely coordinated with other resources, so the total energy consumption will be almost uniform. This suggests that the network will be operated according to the conditions of near-peak load for almost the entire time. First, a decrease in total power consumption led to an increase in reliability by reducing the peak. However, over time, in the face of an increasing load, opportunities for optimal transmission and use of distribution assets, total energy consumption will approach the ultimate capabilities of the power system. Thus, a system will be close to the "limit" much more often, which leads to a greater likelihood of failures and exacerbation of reliability problems, respectively, the need for intelligent networks will increase.

The implementation of the Smart Grid concept provisions for a construction of an intelligent electric power system (IEPS) requires ensuring reliability through the use of modern information and communication technologies (ICT) in order to create an infrastructure that would ensure the coordination of monitoring and regulation throughout the network. Such an IT infrastructure should ensure trouble-free and almost instant two-way interaction between all devices - from individual loads to network control centers, including all basic equipment at the transmission and distribution level. This requires the processing of a significant amount of data for analysis and automation, which is associated with a high-performance infrastructure capable of delivering highly intelligent local pre-second reviews coordinated with higher-level global analysis to prevent or contain rapidly occurring adverse events. The centralized system was too slow for this kind of task. Distributed architecture allows you to create a high-performance infrastructure with a local intelligent pre-second response using modern technologies, which is based on the following:

- advanced telemetry: using PMU technologies for faster, time-stamped, clearer, second-second scans to provide up-to-date information about the network status;
- devices for faster regulation: using powerful electronics for faster automatic regulation, voltage and power flow control at the level of transmission and distribution;
- more robust regulation: actively adaptive regulation of protection and control for a wide area of monitoring and regulation, including an international division of UEPS;
- embedded smart devices: in order to prepare for the use of adaptive intelligent control: diagnosing equipment level failures and poor-quality data identification; operations within the limits are remotely reported by the system operator or regulatory centers; "Intelligent" RAS / SPS etc.; automatic equipment recovery; automatic local regulation; integrated and secure communication systems: distributed and comprehensive communications based on open standards, which allow creating flexible network configurability for the purpose of trouble-free monitoring, automation, two-way communications between all operators and agents;

- use of computer capabilities: trouble-free and secure systems for reliable analysis in order to support the decisions of the operator and stand-alone functional agents controlled by a geographically and time-coordinated hierarchy in IT infrastructure of the network;

- Internet technologies: internet protocols to simplify the exchange of data, a regulatory process and cyber security for implementation of a distributed architecture based on standards with open interfaces.

The hierarchy of control levels in an intelligent electric power system reveals the concept of "smart grids" as a combination of energy and information and communication technologies, representing the possibility of more efficient management of UEPS through the exchange and management of technological and marketing information.

3 Intelligent forecasting in IEPS

The development data of recent years is focused on the development of predictive approaches based on algorithms and methods of artificial intelligence: neural network technologies, expert systems, machine learning models, fuzzy calculations, etc.

Despite the advantages of intelligent forecasting algorithms, indicated in a number of articles of recent years, many researchers believe that the issue of high efficiency, for example, artificial neural networks (ANNs) or fuzzy systems, in solving the problem of predicting aircraft is still open. An intelligent solution to the above cases is the use of hybrid approaches and models, when the combination of various intelligent and traditional models allows you to get the most effective solutions, first of all, guaranteed forecast accuracy. The following combinations can be attributed to promising hybrid models at this stage: fuzzy systems and ANN, expert systems and ANN, Hilbert-Hung transformations with ANN models, etc.

The concept of intelligent monitoring includes the following actions [12-15]: collecting data that is fed to data pre-processing systems that determine the most important and critical data that affect the development of the regime; classification (clustering) of EEC states - the purpose of this procedure is to determine how dangerous a particular state of the system is; interpretation of the resulting clusters (states) so that an operator can develop and implement preventive measures.

For operational dispatching control of the International Electrotechnical Commission (IEC) modes, new means of measuring the regime's parameters of power systems (Phasor Measurement Units, digital measuring instruments) and controlling them (FACTS, energy storage, etc.) should be used, which radically increase the observability and controllability of power systems, modern means of communication, new information technologies and methods of artificial intelligence, high-performance computer tools. They fundamentally change the processes of collecting, processing, transmitting, presenting (visualizing) and using information, and on a new basis, they can

significantly increase the efficiency of operational dispatch control of modes. The development of operational dispatch control methods is associated with IEPS improving information support, automating the preparation of operational solution options, automating management, increasing a share of automatic control in the tasks of regulating and limiting mode parameters, automating the calculation of optimal modes, implementing them, etc., while maintaining control from operational dispatching staff in the required amount [16-19].

Today, the problems of constructing intelligent distribution networks relate mainly to their development on the basis of modern telemechanics and telecontrol facilities, as well as data transmission channels. However, the basis for the optimal functioning of the intelligent network should be provided by control algorithms and software.

The source of information for the operational control system can be the telemechanics devices of the main step-down substations. Distribution network power centres usually have the following telemetry: tire voltage, total active and reactive load, and current load of feeders. If there are reclosers in some feeder branches, the one can additionally obtain information about the current of the site and the voltage of the node at a place of its installation. The recloser at the point of opening the network allows you to control the voltage of the nodes, the difference of which allows evaluating the current efficiency of installed breaks. The observed mode parameters with a fixed operational scheme allow us to estimate the magnitude of nodal loads, using, in addition to telemetry, statistics regarding the loading of transformer points.

Based on the results of an operational assessment of the state of each feeder, it is possible to search for optimal control actions using well-known methods for analysing the modes of electric networks. Today, these methods, as a rule, are developed on the basis of an iterative solution of systems of nodal nonlinear equations and are focused on calculating the modes of multiple closed networks. Unlike the backbones in distribution networks, the design diagram is open in accordance with the operational position of the working openings, the graph of which is represented by a set of branches forming a tree and chords corresponding to disconnected branches.

One of the control tasks in distribution networks is to find the optimal operational circuit and mode parameters when changing loads, supply voltage, etc. Optimization criteria for the hourly step of the graph are power loss, quality and reliability. Often, they are contradictory; therefore, a search for the optimal solution is carried out in the Pareto region. However, such multicriteria problems can be reduced to one criterion. Reliability can be taken into account as a restriction on the acceptable parameters of the mode and fixing some openings in the network to provide power to responsible consumers from two sources.

The quality criterion can be estimated by the minimum release of energy at voltages that go beyond

the permissible region, which can be individual for each characteristic consumer.

Independent parameters for optimizing the parameters may include: voltage level in the power centre, which is determined by the number of a soldering regulation under voltage, a reactive power of small generation plants and the position of the cuts on the full network graph.

4 The development of smart grids concept in Uzbekistan

World experience shows that smart grids can be built in several stages. The first stage is the development of the concept of building a smart grid. The second and third stages can be implemented in parallel: work on the creation of interfaces that can connect the modernized facilities of the main electric grid economy with generation and consumers which is simultaneously carried out with the development of pilot projects, within the framework of which technologies are being developed for the creation of intelligent power system (IPS). Fig. 1 highlights the basic concept for smart grid development in Uzbekistan.

Possible list of stages of the concept for creating smart grids in Uzbekistan:

1. New solutions and technologies (breakthrough and improving): new types of electrical equipment, including new systems for monitoring the condition of equipment, self-recovering, relay protection and emergency automation, energy metering systems.

2. Information interaction and control systems: the creation of information infrastructure, its integration with the electric grid, information support and optimization systems for managing all processes in the electric network.

3. Regulatory aspects: a new range of services that is provided by electric power industry entities; normative distribution of roles in the interaction of electric power industry entities in the new conditions, including the development of network rules.

4. Creation and implementation of pilot projects (energy clusters): integration of electric grid and information infrastructure, integration of all types of generation, energy storage systems; creation of an all-regime management system with full-scale information support, optimization management systems; selection of zones for the implementation of pilot projects, assessment of technical, economic, environmental and social effects.

5. Duplication of results, cluster consolidation, creation of intelligent energy systems in Uzbekistan, replication of the successful results of pilot projects, integration of energy clusters into a single electric power system.

Expected results from the implementation of Smart Grid:

- 1) the most efficient use of energy resources;
- 2) removing the network economy from the crisis by replacing obsolete equipment;
- 3) reduction of electricity losses, its significant savings;

- 4) reduction of emergency shutdown time; increasing the efficiency of loading electrical equipment;
- 5) increase in volumes of electricity transit by 15–20% without the construction of new network facilities;
- 6) reduction in energy production costs;
- 7) reduction in the cost of utilities;
- 8) the use of alternative energy sources;

- 9) reduction of the environmental impact of energy facilities (reduction of CO₂ emissions in the atmosphere);
- 10) providing a model of two-way communication with the consumer;
- 11) identification of a theft of electricity, equipment damage and their timely elimination.

Fig. 1. The basic concept of smart grid development in Uzbekistan

Advancement of the Smart Grid concept requires a change in many elements of the power system. Their success depends not only on installing new meters and improving the efficiency of electricity supply but also long-term measures are needed, such as the development of power electronics and devices based on it, primarily various kinds of network-controlled devices (flexible AC transmission systems – FACTS) to increase line throughput and ensure stable operation of the power system under various disturbances, widespread development of distributed generation and renewable energy sources. It should be borne in mind that various technologies of the smart energy system are being introduced on the market and at different speeds.

Another obstacle to the comprehensive implementation of the concept of an intelligent energy system is the difficulty of reconfiguring the relationships between electric power entities, since the implementation of Smart Grid concerns all direct participants (individuals and legal entities of any form of ownership) of the processes of production, transmission, distribution, consumption, purchase and sale of electric energy.

Accordingly, the scope of such a project is commensurate with the scale of creation of a new electric power system, including the depth of elaboration and detailing for each individual power receiver.

The introduction of innovative technologies is connected with the solution of two critical issues that will allow a fresh look at the relationship between the consumer and the energy company: providing the consumer with two-way control technology that can help manage the declared peak power; an implementation of dynamic pricing in the retail electric energy market, stimulating consumers to change their usual load schedules.

5 Conclusions

Thus,

- the tasks of the electric power systems development were formulated,
- the main directions of the intelligent electric power systems development were evaluated,
- the necessary technological basis was described,
- the requirements for the areas of use of IEPS were sufficiently detailed,
- the construction features and the components of intelligent control systems were presented.

The introduction of Smart Grid leads to a change in the energy system's functioning technologies (direct consumer load management, dispatch modelling, real-time distributed system analysis tools, demand response analysis, system emergency recovery support, etc.), to a

change in the energy management system (new architecture program security, management system), to the formation and growth of new markets. It is possible that smart grids will not only contribute to the modernization of the Uzbekistan energy system, but will also help to create a new electrical base for the production of equipment.

Abstract. The issue of energy-saving and energy efficiency is actual at the present-day development of Ukraine's economy. The imperfective system of energy ensuring as the result of inefficient energy resources utilization is a characteristic feature of the state. The analysis of ensuring energy resources applied to Dnipropetrovsk Region as one of the leading industrial regions of the country is presented in the article. The availability of reserves and production of fuel resources was analyzed in it. Distinctive features of energy resources consumption with the aim of assessment general and partial indexes of energy ensuring and fuel power-intensity of the region's economic complex are highlighted in the work. The tendencies and perspectives of energy consumption development of the Dnipropetrovsk Region were analyzed herewith.

Introduction

The problems of ensuring any country with its own fuel-energy resources are considered as the most acute and urgent ones because they refer to a country's energy safety. Under conditions of formation and realization of energy ensuring strategy and optimizing energy consumption resources, which are the basis of a territory economy development, the issue of sufficient volume of fuel energy resources availability for renewable processes in industries of the national economy as well as ensuring energy, economical and correspondently national security arises acutely [1].

Fuel-energy resources as any other resources are located very much unevenly on the territory of the country. So there arises the necessity of exploring deposits, their extraction, beneficiation, processing and transportation which stipulates the development of mining industry. Energy safety, in its turn, demands the assessment of resource and energy potential of the territory, includes the control over energy resources, energy-saving and energy efficiency.

Crisis periods in economy, fuel price fluctuations and the present-day environmental challenges demand a transition from increasing output of traditional to renewable energy resources. Monitoring the resource base of fuel energy raw materials remains actual, in particular, the regional analysis of characteristic features of consumption and ensuring fuel energy raw materials by individual regions of the country.

The issues of the country's (a region's, a territory's) energy safety were comprehensively researched in the works of A. Yerina [22], O. Kolodiazna [22], V. Lir [17], V. Mykhailov [11], M. Mazur [3] et al. Ensuring mineral energy resources and rational nature

management were considered in the works of M. Korzhniev [23], Ye. Yakovliev [23], M. Syvyi [20] and others. They concerned the analysis of the present-day status of Ukraine's mineral-and-raw material base, solving the problems of development and restructuring mineral raw deposits, improvement of the system of state management for mineral resources use. Much attention is paid to the problems connected with the usage of non-traditional sources of hydrocarbons. S. Vakarchuk [9], M. Syvyi [21], N. Khomenko [10] carried out the study of methane use and extraction possibilities at coal deposits, shale gas – by S. Vakarchuk, O. Zeikan and others [9]. Hence, the problem of formation of stable energy ensuring remains actual and demands further researching.

The purpose of the research is the analysis of energy resources consumption by the Dnepropetrovsk Region and providing its needs for fuel-and-energy raw materials; assessment of the role and place in the structure of consumption energy resources of own extraction, as well as the present status of energy extracting industry; revealing the problems and perspectives of its development.

1 Energy resources consumption in the Dnepropetrovsk Region

The Dnipropetrovsk Region is one of the major industrially developed territories of Ukraine, the development of which is grounded on mineral resources extraction and processing, steel making, mechanical engineering, chemical industry that have high indexes of power-consumption. The Region's share in the national industrial production made up 22.5% in 2018 and the Region ranks the first place in Ukraine by this index.

* Corresponding author: panteleeva4y@gmail.com

The Region is also one of the biggest energy resources consumers (Fig. 1) [2].

Fig. 1. The place of the Dnipropetrovsk Region among Ukraine's regions in relation to various energy sources consumption in 2018 (on the basis of Dniprostat data).

In the opinion of M. Mazur it is typical for the territory to use fuel energy resources (FER) in stages: ensuring formation of the resource base; fuel energy resources extraction; energy generating and transformation; fuel and energy transportation; energy and fuel consumption. Each stage is characterized by indexes of power-consumption, usefulness of the resources, fuel energy resources losses.

Reducing in losses at each stage will allow to involve energy-saving potential, and the use of unconventional sources of energy will allow replacement potential of nonrenewable resources by renewable ones and minimize the negative environmental impact [3].

By the year 2018 in the structure of Ukraine's energy resources consumption the volumes of coal prevailed (39.2%) that of coke and semi-coke from coal; gas coke (28.6%) and natural gas (13.8%) [4]. Fig. 2 illustrates energy resources consumption from 2011 up to 2018 period. The tendency of decreasing natural gas consumption and increasing coal and coke usage was observed through this period.

Fig. 2. The dynamics of energy resources consumption in the Dnipropetrovsk Region during the period of 2011–2018 [4].

The generalized index characterizing a region's economic growth at the regional level is Gross Regional

Product (GRP), which can be applied to calculation a production's fuel energy capacity. Economical indexes of the Region during the years 2014–2015 had the tendency of decreasing due to the economic crisis. General drop in the Region's economy at that period amounted almost to 12.5%. Since 2016 economic situation in the Region has stabilized and the rates of growth have been gradually recovered (Table 1). The coefficient of fuel energy capacity index calculated by the authors is a ratio of GRP to the fuel consumed. It illustrates general efficiency of fuel consumption in the Dnipropetrovsk Region on the basis of GRP ratio per one hryvna (UAH). As seen from Table 1, fuel consumption in the Region has a stable tendency to decrease, though the level of fuel energy capacity remains rather high. It is important for the Region's steady development that economic growth would be synchronized with decreasing of GRP fuel energy capacity.

Table 1. The dynamics of general level of fuel energy capacity the Dnipropetrovsk Region during 2010–2017 [GRP] [5].

Years	Fuel consumed (thousand ton of conditional fuel)	GRP in actual prices (million UAH)	Fuel energy capacity coefficient (kg, conditional fuel / UAH)
2010	23074,6	116136	0,198
2011	22838,9	140020	0,163
2012	21980,3	147970	0,148
2013	21199,1	152905	0,138
2014	18159,8	176540	0,109
2015	21200,0	215206	0,098
2016	19203,0	244478	0,078
2017	19900,0	313830	0,063

In the structure of the fuel consumed according to the types of economic activities by the main consumers there are enterprises of steel production, their share made up 63.1% of total volume of consumption. So, the measures for energy-saving in steel production are of top priority.

There are over 500 industrial enterprises on the territory of the Region. From the territorial point of view, the main fuel consumers are three cities: Kryvyi Rih (46%), Dnipro (19%) and Kam'yanske (18.3%). Unit weight of coke consumption by Kryvyi Rih enterprises makes up 65% of total consumption, natural gas – 47.4%, coke – 30.4% [6].

Thermal power stations are significant sectoral consumers of energy resources in the Region: Kryvyi Rih TPS (2892 MW output) and Prydniprovsk TPS (1765 MW output) which are included into the united power system of Ukraine and they are coal-based operating [6].

The Dnipropetrovsk Region is one of the most urbanized regions in Ukraine. 20 cities, 46 towns and 1435 villages are located on the Region's territory. The share of city population in the Region makes 83.61% as per average index of 69.23% in Ukraine. That is why the major Region's gas consumers are the population, industry and government-financed organizations (Fig. 3). The statistics data analysis of natural gas consumption by the population in 2018 showed that volumes of

realization dropped by 20% as compared to the previous year due to gas price changes, and the use of firewood for heating raised almost by 6 times.

Fig. 3. Natural gas consumption by consumer categories in the Dnipropetrovsk Region, thousand m³ (2018) [6]

To make assessment of the Dnipropetrovsk Region ensuring with its own fuel energy resources (hydrocarbons, hard and brown coals) it is necessary to analyze the present day status of their deposits, demand, the ways of technical re-equipment and restricting the mining industry.

2 Fuel mineral resources extraction in the Dnipropetrovsk Region

The deposits of fuel energy raw materials in the Dnipropetrovsk Region are exploited for a long time (gas, oil, hard coal) hence, some of them (brown coal) remain unclaimed or need further researching (unconventional types).

2.1 Natural gas and oil

15 hydrocarbon deposits have been registered [7] in the Dnipropetrovsk Region, the major part of which are integrated ones, namely 4 gas fields, 5 gas-condensate fields, 7 oil-and-gas-condensate fields, out of which 12 are exploited and 3 are being explored.

Oil and gas fields are located in the north-east of the Dnipropetrovsk Region and belong to the Dniipro-Donetsk oil- and gas-bearing region (DDOGR). Referring to tectonic aspect DDOGR is located within the Dniipro-Donetsk depression (DDD). The depression was formed with thick rock sediments aging from Middle Devon to Neozoic.

Hydrocarbon deposits on the territory of the Dnipropetrovsk Region belong to Rudenivsko-Proletarskyi oil-gas-bearing region the main part of which is located within the Poltava Region. The region is attached to the south-east side-board of the DDD and presented by hydrocarbon deposits in sediments of the Middle, Lower Carbon and Devon. In the boundaries of the Dnipropetrovsk Region there is Mykhailivsko-Leventsivska zone of oil-gas accumulation.

Many of the explored deposits belong to the small categories having less than 5 billion m³ of gas reserves.

Separate deposits of medium size (*Proletarske, Ul'yanivske*) are substantially exhausted and do not make any difference from others (Table 2). The deposits' free gas is high-caloric (30-40 thousand kJ), being mainly sulfur-free, with minor nitrogen and carbon-oxide gas content. Gas consistency in relation to the air varies from 0.556 to 1.1. The current state of fixed condensate in gas is changing from 1 to 2 265 g/m³. An average ethane, propane, butanes content in free gas makes correspondently: 5,58; 2,06; 0,74%; helium – 0.07% [7].

Gas reserves make about 1.5%, oil reserves 0.9% and gas condensate 2% of the national ones (Table 2).

Table 2. Distribution of reserves (by 01.01.2019) and hydrocarbon extraction (2017) among the deposits in the Dnipropetrovsk Region (on the basis of Geoinform data).

Three projects (two deposits and one area) Ryaskivske, Musiyenkivske, East-Golubivsk are prospective for oil and gas extraction after carrying out a complete volume of geologic exploration works. But a detailed geologic exploration of the underground resources and provision of the necessary facilities for the deposits demand considerable investments [7].

The following companies such as Joint Stock Company “Ukrasvydobuvannya” and PJSC “Ukrnafta” are dealing with oil, gas and gas condensate extraction on the territory of the Region.

As seen from the Fig. 4, there exists a considerable unbalance in the Region between the levels of consumption and supplying its own energy resources. Energy safety demands searching for efficient decisions

related to regulation of available resources consumption.

Fig.4. The dynamics of gas extraction and consumption in the Dnipropetrovsk Region in 2013–2017 [4].

The tendency in drop of the level of natural gas consumption and its import in Ukraine has been observed since 2016, which is undoubtedly a positive factor. At the same time, by the current decreased level of consumption – over 30 billion m³/year – the country is not able to provide itself with its own resources (20 billion m³/year). The Government’s Decree “On Approval the Concept of Gas Extracting Industry Development in Ukraine” dated on December 28, 2016 No.1079 set the target: to produce 27 billion m³ in 2020, though it is not realistic due to the lack of financial means for substantial expanding geologic exploration works, introducing up-to-date methods of intensifying exploration, maintenance and development of gas industry.

At present, there are only solitary instances of applying up-to-date methods of intensifying exploration. Beginning from September 2016 JSC “Ukrasvydobuvannya” got additional 261 million cubic meters of gas in the Ul’yanivske field at the cost of carrying out works for beds (layers) intensification by the method of hydraulic breaking (HB). Hydraulic breaking (HB) works were performed by the Belorussian state-owned company “Belorusneft”.

2.2 Brown coal

Brown coal fields are concentrated in Verkhnyodniprovsk, Synel’nykove and Petrykivka districts of the Dnipropetrovsk Region and attached to the Dniprovsk brown coal field of the West Donbas. The brown coal deposits belong to the Paleozoic (Lower, Middle Carbon) and Neozoic ages (palaeogene).

The Paleozoic deposits are spread out in Petrykivka geologic-industrial district of the West Donbas and attached mainly to Samara coal-bearing, partially to Mezhive formation of Lower and Mospine formation of Middle Carbon. Highly metamorphized brown coal of Petrykivka deposit with total reserves of 0.3 billion ton belongs mainly to so-called saline coals and has the increased content of water-soluble sodium salts, for this reason its exploration has been stopped.

Coal-bearing Palaeogene (Neozoic) age deposits are attached to multiple depressions on the surface of Ukrainian shield. Paramount volume of balance reserves of coal industrial categories is concentrated in the Dnipropetrovsk Region – not less than 1 billion ton, or 55.6% of the total reserves in the Basin. The Dnipro Basin deposits are suitable for open exploitation of such categories as A+B+C₁ – 519.6 million t, C₂ – 8.9 million t; extra-balance – 32.0 million t. The balance reserves of A+B+C₁ categories, suitable for the deposits open mining, are concentrated mainly in the Kirovograd (254.5 million t – 49%) and the Dnipropetrovsk Regions (246.4 million t – 47%).

On the territory of the Dnipropetrovsk Region and partially in the neighboring regions there are three geologic-industrial districts: Verkhnyodniprovsk (partially in the Kirovograd and Zaporizhzhya Regions) – 19 deposits; Orihiv in the Zaporizhzhya and Dnipropetrovsk Regions – 2 deposits (*Orihivske and Sanzharivske*) and 4 areas, Kryvyi Rih in the Dnipropetrovsk, partially in the Mykolaiv and the Kherson Regions – 4 deposits (*Apostolovske, Veselo-Ternivske, Guriyske, Pichuginske*).

Geologic structure of the deposits is presented with spongy, sandy-and-clay rocks of Paleogene, Neogene and Quaternary ages of cover thickness up to 100 m varying mainly from 50 to 70 m, which fill depressions in crystalline foundations. The main coal-bearing concentration is attached to the Buchatska formation of the Eocene section of the Paleogene system. This factor determines the deposits and sections morphology, which have lens-like shape deposits of the complicated irregular configurations. Deposits extensions vary from several meters up to several kilometers.

General number of beds makes up from 1 to 3, average covering thickness accounts for 3–6 meter, up to 20 meter at maximum. Occurrence depth of coal beds varies from 10 to 150 meter. Coal is soft brown, humite and humite-lipto-biolithe.

Brown coal reserves of the Dniprovsk Basin and its distribution among deposits and administrative districts of the Region are shown in Table 3.

Occurrence of coal beds in the thickness of spongy sandy-and-clay rocks causes a strong water-cut of plots. The coefficient of rock moisture capacity of the normally operating enterprises usually makes up about 10 m³ of water per 1 ton of coal extracted. Water-bearing horizons, which complicate the mining works, are distinguished into under-coal one which is located in the rocks of under-coal and over-coal bed which occurs higher of coal beds.

Brown coal is suitable for caking, semi-coking, gasifying, production of artificial earth wax.

The reserved plots for brown coal open-pit mining are at Verkhnyodniprovsk and Synel’nykove deposits in the Dnipropetrovsk Region (Table 3).

At Verkhnyodniprovsk deposit the reserves for open mining account for 146.44 million t. Mining and geologic conditions are favorable: coal bed thickness is 10.6 m; industrial coefficient of uncovering makes 6.6 m³/t; humidity 51%; ash content 18.7%; bitumen content 8.3%; coal combustion heat 2290 kcal/kg. It is

possible to arrange a quarry here with annual output of 4.0-4.7 million t. Apart from favorable geologic conditions the deposit is located in ecological zone of the Dnipro river. Its allocation for mining may have environmental impact upon the river.

Table 3. Brown coal deposits of the Dnipropetrovsk Region.

Petrivska plot with reserves of 73.28 million t and 9.1 m³/t coefficient of uncovering has been explored at Synel'nykove brown coal deposit with total reserves of 350 million t for open mining. Coal humidity is 58%; sulfur content – 4.8%; ash content – 20.8%; bitumen content – 7.4%; coal combustion heat amounts to 1810 kcal/kg. Mining and geologic conditions are difficult.

Other deposits in the Dnipropetrovsk Region were explored earlier and can be mined exclusively by the

underground method.

Taking into account the tendency of curtailing the usage of nonrenewable natural resources the beginning of brown coal mining in the region is economically unreasonable.

2.3 Hard coal

Ukraine takes first place in Europe relating to hard coal reserves, its resources account for 117,2 billion t, and the explored coal makes up 45.8 billion t. Out of the explored reserves 25 billion t belong to the West Donbas. Within the territory of the Dnipropetrovsk Region there are deposits of Pavlogradsk-Petropavlivsk, Novomoskovsk and Petrykivsk geologic-industrial districts. Coal mining is carried out only in Pavlogradsk-Petropavlivka geologic-industrial district where 10 mines of JSC "DTEK Pavlogradvugillya" operate (Table 4).

Table 4. Coal output at JSC "DTEK Pavlogradvugillya" mines in 2018 [8].

Mine's name	Reserves by 01.01.2017	Output, t	+/- as to the preceding year
Stepova	1932289	231212	20194
Pavlogradska	45467	61005	-143495
Yuvileiyna	73306	133848	46924
Blagodatna	81420	139900	-30873
Ternivska	60892	119490	990
Samarska	77756	154429	13005
Dniprovska	127504	102362	-23080
Geroiiv Kosmosu	192406	265118	-452
West-Donbaska	233079	131100	-36556
Stashkov mine	51973	191079	91631

The area of the part of deposits being mined accounts for about 600 square kilometers. Industrial coal-bearing is attached to sediments of Samara formation C₁³(C) of the lower part of Serpukhov layer of lower Carbon. Samara formation is characterized by a considerable development mainly of low-yield coal beds and interfacial layers. Coal beds are alternated with argillite, aleuroliths, sandstones and lime-stones.

Coal beds of C₁³(C) formation of Pavlogradsk-Petropavlivsk geologic-industrial district corresponds to long-flaring; long-flaring and gassy; gassy brands. Coal of long-flaring brand is partially spread in the western part of Pavlogradsk-Petropavlivsk geologic-industrial district, long-flaring an, gassy – mainly in the central part and gassy brand – in the eastern part. Coal of "Geroiiv Kosmosu", "Blagodatna", "Pavlogradska", "Ternivska", "Dniprovska" mines belongs to long-flaring, gassy brand, the rest – to gassy brand. Coal of long-flaring brand can be used as energy and municipal fuel with a prospect of using it in chemical and partially in coke-chemical industries. Coal beds of Samara formation of gassy brand in Pavlogradsk-Petropavlivsk district, as of that in West Donbas in general, do not differ for their petrography content from coal of long-flaring, gassy brand. In the long term the coal reserves of long-flaring, gassy brand are a basis for production of squeezed coke and obtaining synthetic fuels. At present

the main purpose of coal use is power engineering. The main purpose of gassy brand coal usage in the eastern part of Pavlogradsk-Petropavlivsk geologic-industrial district is in coke-chemical industry.

A considerable part of the area under extraction comes to the river overflows, industrial and civil objects. Under the overflows of the Samara, Ternivka, Mala Ternivka rivers 186.3 million t of coal are bedded and under civil and industrial structures – 412 million t [7]. Such settlements as Blagodatne, Verbky, Ternivka, Rosyshky, Samarske and others get location in mining zone. Moreover, in the area of coal mine fields there runs Kyiv – Donetsk motor road and the railway sections.

The potential capabilities for increasing energy and coke coals are available in the Dnipropetrovsk Region.

Large reserves of energy coal are concentrated in Novomoskovsk District, but this coal belongs to a saline one. It has an increased content of water-soluble salts of sodium inherited from the marine conditions of coal accumulation [7].

Taking into account the world tendencies towards curtailing the use of energy coal, its production must be carried out within the volumes of existing needs. Hence, due to available technologies, steel production retains the need of steadily supplying the industry with coke coal. Therefore, there is an acute problem of technological re-equipment in coal mining industry, which will allow optimizing coal output volumes in the region.

3 Alternative sources of hydrocarbon raw materials

3.1 Methane gas of coal deposits

In the context of energy source diversifying the problem of utilizing alternative types of hydrocarbon raw materials arises acutely. Coal-bearing deposits of Donbas (coal beds as well as coal-bearing rocks), which contain methane considerable resources, can serve for its industrial production and should be taken up as gas-coal deposits. Methane of coal deposits is a widespread energy raw material and its reserves are rather huge, and the real volume suitable for extraction exceeds 3.0–3.5 trillion m³, which overruns substantially gas reserves of the rest fields of Ukraine. It is necessary to carry out gas-coal deposits mining in an integrated way for separate extraction coal and methane. In so doing, the methane resources are estimated as an accompanying useful mineral. It is technologically necessary to remove it for providing safe works during coal mining operation, or as an individual useful mineral which is extracted irrespective of coal beds mining on the principles of economic feasibility and profitability.

By the assessment of national and foreign experts, Ukraine takes the fourth place in the world after China, Russia and Canada for its methane reserves potential at coal deposits.

Total resources of the mine methane in rocks and coal beds vary by different assessments from 4-6 up to 22.2 trillion m³. The industrial share makes 11.9 trillion m³ out of 3.3 trillion m³ forecasted are suitable for extraction [9]. A considerable part of total methane

reserves in coal-bearing rocks makes up occluded and fixed methane for extracting of which introducing efficient technologies for mining works and technical tools by using foreign countries' experience are required.

Methane as an accompanying useful mineral is contained in coal beds of Carbon age in the east of the Region within Pavlogradsk-Petropavlivsk geologic-industrial district. Natural methane-bearing capacity of coal-bearing deposits changes, at average, from 5 up to 30 m³/t of dry ash-less mass [7]. Coal beds are characterized by primary and post-sedimentation folding and are natural traps, where methane is in a free condition. The depths from 350 m to 1000 m are considered optimal for methane extraction out of coal beds of low-medium and medium grade of metamorphism. The mines of Pavlogradsk-Petropavlivsk district of West Donbas correspond to such geotectonic conditions. Regional strata dislocation is not high, thickness up to 3 km with minor cata-genetic transformations, increased porosity and perviousness. Coal beds covering consists of rocks containing aleurolite-and-argillite with minor layers of sandstones, which enables methane conservation. Collectors of methane serve fractured reservoirs [10]. Coal mine fields of Pavlogradsk-Petropavlivsk district are located within the Central graben (sunken block) and are limited by Shevchenkivskiy and Bogdanivskiy faults. Coal beds plunge in monoclonal way at an angle 3-5° to the north, north-east with rocks strike in the western and north-western directions. During research it was determined that positive gas anomalies within Geroiyv Kosmosu mine of Pavlogradsk-Petropavlivsk district are located within synclinal flexure, which stretches alongside Bogdanivskiy fault. Positive anomalies of free methane content deviation on the mine's field are connected with synclinal folds, one of which was formed near Bogdanivskiy fault and another – in a syncline wing near Blagodatnenskiy fault. Separate anomalies are situated within great anticline structure. Data statistics processing of nine mines' fields in Pavlogradsk-Petropavlivsk district performed by N. Khomenko showed that in folds and wings of syncline structures over 50% of additive gas-bearing anomalies and 67% anomalies with free methane content concentrate [10].

Research works for studying possibilities of industrial extraction methane from Donbas coal thickness with selection of plots for setting up pilot projects were carried out [11] among the others in Petrykivka-Novomoskovsk area (southern bench of marginal through part of the Dnipro-Donetsk depression) and in Pavlogradsk-Petropavlivsk (in the southern zone of Donbas minor folding).

In Pavlogradsk-Petropavlivsk district the resources of HC (hydro-carbonaceous) gases in coal beds and layers in the operating mines (mine fields) account for: in coal 11.7 billion m³, in satellites CK = 0.5 (total) 6.1 billion m³ with reservoir thickness of 0.3 m – 2.3 billion m³, (on the exploration plots) in coal 4.4 billion m³, in satellites (total) 5.8 billion m³, with reservoir thickness of 0.3–2.3 m.

Comparing to other geologic-industrial districts of Donbas, where hydro-carbonaceous gas resources were

calculated, Pavlograd-Petropavlivsk district is characterized by mean values of the reserves (18 billion m³). It is suggested to be considered as a territory of the second turn, which must be developed by using an experience obtained on the territories of the first turn [10].

The present geologic survey works (GSW) with the purpose of developing methane extraction technologies from coal beds are carried out on 16 plots in coal-bearing Donbas under special permission. But the lack of occluded and tied gas extraction technologies does not allow to expect positive results of geologic survey works (GSW) due to the obvious absence of technical-and-technological equipment required for these kinds of works.

Research-and-commercial extraction of methane-gas is carried out in Lysychansk-Toshkivka area, where methane output amounted to 0.84 million m³ in 2017. Methane loss due to coal mining amounted to 126.52 million m³ in 2017.

3.2 Shale gas

Considerable perspectives for further increasing resource base of hydrocarbon gases in the Region and in the state in general are associated with shale gas resources development [9].

By the assessment of [9] who researched relationships of spatial and age-related rock expansion for perspective shale gas in Eastern oil-gas-bearing district of Ukraine within north-east part of the Dnipropetrovsk and partially of the Kherson regions there was singled out Zakhidnomykhailivsko-Pivdenoblyznyiukivska perspective zone. It is attached to the southern Dnipro-Donetsk depression/fault rim. The zone extent makes up 128x24 kilometer approximately. Occurrence depth of sediments covering of Lower Carbon here varies from 1500 to 4000 m.

Within the Dnipropetrovsk Region there are located Bagatoiska, Pereschepyne, Lychkove, Kremenivka, Kotivka, Kateryniva, Kernosivka, Mykhailivsko-Pivnichnominivska, Leventsivka areas, in which mainly of them traditional oil-gas fields are exploited. Sediments of Lower Carbon, Upper-Vize and Lower-Serpukhov sub-layers are perspective ones for shale gas exploration on this territory [11]. In the cut of Upper-Vize sediments the perspective clay thickness are made up mainly of dark-grey and up to black argillites. Lower-Serpukhov sub-layers rocks are presented mainly by dark-grey argillites with minor interfacial layers of aleurolite, sometimes siderites or hard coal. By prior assessments [9] the production resources of shale gas of low-hard coal clay sediments within the whole perspective zone of 3027 square kilometers amount to 1756.7 billion m³ including free gas – 801.3 billion m³ and occluded gas– 149.9 billion m³. Resources density on this territory amounts to 580.3 million m³, sediments occurrence depth is in the interval of 2500–4300 m. By its geologic-production criteria Zakhidnomykhailivsko-Pivdenoblyznyiukivska zone is the top-priority object for geologic-surveying works in shale gas exploration [9].

4 Perspectives of energy industry development in the Dnipropetrovsk Region

Thus, the ensuring its own fuel-energetic resources and their consumption within the Region are obviously unbalanced: steady power supply and efficient utility of energy resources in the Dnipropetrovsk Region are of top-priority problems which demand solution in order to exclude the drop in economic and social development of the society.

It is worth mentioning the following factors that influence energy efficiency of the Region's economy:

1. domination of power-consuming industries in economic structure;
2. tear and wear of fixed assets and out-of-date technologies;
3. the absence of the unified monitoring system and control over energy consumption;
4. the lack of introducing innovative technologies mechanisms;
5. the absence of anti-monopoly mechanisms at national and regional levels.

Energy efficiency of economy is directly connected with the use of fuel-energy resources (FER) nature, which must ensure steady economic development. National researchers understand the steady economic development as satisfying the needs of social-economic systems without limiting possibilities of the coming generations with regard to satisfying their needs [3, 12]. So, FER utility and energy efficiency should be considered in view of the concept of ecological efficient production, ecologically justified consumption and efficient management [3].

Experts mark out several criteria of FER rational usage [3]:

1. minimizing resources loss in the processes of production, supply, distribution, transformation and consumption;
2. attraction and utilization of secondary energy resources and waste products for their production;
3. development of market mechanisms in the sphere of ensuring and using energy resources;
4. increasing efficiency of FER consumption at the cost of introducing efficient technologies and increasing FER consumption efficiency;
5. maintenance of FER incremental value per capita in order to provide saving of natural capital value;
6. widening the sphere of utilization renewable energy sources in FER production and consumption;
7. limitation the government's interference which threatens unbalancing market regulation mechanisms of FER consumption and socio-economic development.

Providing energy safety of the Dnipropetrovsk Region as an industrially developed district at the expense of increasing energy efficiency in economy and developing alternative power industry is one of the top targets of the Dnipropetrovsk Region Strategy Development for the Period up to 2035, which is the basic document of the region's power engineering development. The Strategy envisages taking into account

the economic, social and environmental priorities of energy-saving, energy efficiency and the region's power engineering development.

As mentioned above, high fuel consumption and a large portion of mineral fuel in the region's energy balance together with out-of-date technologies and inefficient exhaust gas-cleaning systems lead to high level of atmospheric pollution. That is why the major strategic targets [6] of the Region's power engineering development are determined as follows:

1. energy safety (planning of measures related to energy-saving and increasing energy efficiency level, decreasing GRP energy consumption capacity and energy renewal sources development);
2. "green" economy (promotion economic growth and decreasing power unbalance owing to renewal energy development);
3. clean environment (improvement of the human environment and quality of life).

So, in 2018 on the territory of the Dnipropetrovsk Region 13 solar power stations (SPS) were put into operation amounting to 38 units in total. In 2018 SPS of the region produced 37 million kW/year of electric power, which corresponds to annual consumption by Novomoskovsk District. The most powerful solar station operates in Nikopol (32 screens of 10 MW output) built by investors from Canada (project cost EUR 11 million). Chinese investors are building SPS for EUR 230 million near Starozavodske village of Nikopol District.

On the Region's territory six biogas installations have been put into operation and the development of wind-power engineering is being planned.

5 Conclusions

The analysis of consumption and energy resources ensuring of the Dnipropetrovsk Region performed by us allows to state as follows:

1. In the structure of the Region's consumption energy resources hard coal prevails (39.2%), coke and semi-coke of hard coal; gas coke (28.6%) and natural gas (13.8%).
2. The main consumers of energy resources in the Region are steel producers, the share of which amounts to 63.1% of total volumes of consumption, electric power stations, population and industrial enterprises.
3. In the Region there is actual unbalance between the levels of ensuring own natural gas resources and its consumption which demands investment into exploration and mining works at the deposits of traditional and alternative energy carriers.
4. At present, brown coal mining at the known deposits in the Region is not reasonable due to the limit of their reserves and of problematic methods of their extraction.
5. In the Region there are potential possibilities for increasing output of both hard coal and coking coal, but its mining should be limited to the available volumes. Technological re-equipment became actual in coal mining industry, which will allow optimizing coal extraction in the Region in view of ecology problems.

6. Methane as an accompanying useful mineral is present in coal beds of Carbon age in the north of the Region within Pavlogradsk-Petropavlivsk geologic-industrial district.

The district with average values of the reserves (18 billion m³) is proposed to be considered as a territory of the second turn, which must be developed by using an experience obtained in gas extraction on the territories of the first turn with considerable reserves.

7. For the perspective exploration of shale gas in the Region are sediments of Lower Carbon, in particular Upper-Vize and Lower-Serpukhov sub-layers on the territories where traditional oil-gas deposits are exploited. Top-priority object to carry out geologic explorative works for shale gas is Zakhidnomykhailivsko-Pivdennoblyznyukivska zone. The production resources of shale gas of low-hard coal clay sediments within the whole perspective zone amount to 1756.7 billion m³ including free gas – 801.3 billion m³ and occluded gas – 149.9 billion m³.

8. The solution of the problem of energy intensive industries in the Dnipropetrovsk Region has a complex character and requires finding efficient solutions concerning regulation of energy resources consumption by using stimulating, compulsory and educative measures. Top-priority directions of the state and regional policy in the sphere of energy-saving must be decreasing energy intensity and introducing alternative types of energy.

Photovoltaic and wind energy: challenges and solutions in desert regions

Ali Al-Dousari*, Waleed Al-Nassar, and Modi Ahmed

Kuwait Institute for Scientific Research, Environmental and Life Sciences Research Center, Al-Jaheth Str., Shuwaikh, 13109, Kuwait

Abstract. In desert areas, some challenges have the prospective to reduce photovoltaic energy production. These are the creation of finely crusted carbonates and/or mud coatings resulted from fallen aerosols and dust during humid conditions. These challenges that greatly affect solar panel planes, as well as wind turbines, were allocated to accomplish the practicability to establish wind and/or photovoltaic energy systems in Kuwait. It was concluded that solar cells are not the best appropriate energy source in Kuwait due to the above-listed challenges; therefore, substitute renewable energy types are considered more practicable. After one year of operation at photovoltaic units and wind turbines in Kuwait, the outcomes show that wind turbines record production energy numbers that go beyond the production average. This was connected with high capacity factors during one year, consequential in an annual power production that is 2.3 times greater than that of solar panels; running 450 homes compared to 199 homes for photovoltaic (PV). Bubiyan Island and west of Kuwait are the most suitable potential location for wind farm establishment. Several control measures including the establishment of green belts and plantation of native shrubs were found proper in reducing dust by 64.5% and 68.4, respectively.

1 Introduction

Globally, the consumption of wind and solar energy is expected to increase more than any other mid-century energy source [1]. Solar and wind energy as a renewable energy source, therefore, conquer the peak between various alternative energy sources and are slowly adapted in multiple applications [6]. In desert regions, several environmental problems affect the photovoltaic panel such as darkness, air pollution and dust. Wind and photovoltaic energy are quiet, abundant, environmentally friendly, and a renewable energy source [8]. Solar radiation, dust and relative humidity in the Middle East have a negative impact on the Arabian Gulf region [13]. Such a challenge is common in nature and is therefore likely to apply passive and active approaches in desert regions according to their specific conditions [9]. At a certain geographic location, awareness of these challenges is vital in establishing any clean energy systems and in estimating their output and efficiency [3]. Awareness of these challenges is also a prerequisite for all solar and wind systems to be modeled and planned and valuable for studies on the balance of atmospheric energy, air quality and climate [14]. The concerns of social public engagement and sustainable expansion in the region, solar energy development are discussed along with the necessity to develop the human capital needed to address alternative photovoltaic energy challenges from a technical and social point of view [10]. In addition, wind energy efficiency problems require the

careful attention of wind properties such as average wind frequency distribution and speed [14].

The Gulf Countries (Saudi Arabia, Qatar, Kuwait, UAE, Oman, and Bahrain) are at peak loads deficiency and high risk of power, in addition to consuming oil and gas resources to meet increasing energy demand [4]. In Kuwait, environmentally clean energy systems will lead to a modern electrical network, more job opportunities, a more efficient power supply, and a better regional image in a cleaner environment [11]. Among the many alternative renewable energy sources, photovoltaic power generation is the most practiced in the Arabian Gulf countries [2]. The monthly solar consumption in Kuwait is approximately 9-11 hr/d with a mean daily solar insolation of more than 7.0 kWh/m² [8]. On the other hand, aeolian dust is a common weather phenomenon in marine and terrestrial [1] environments within Kuwait. In the northern Arabian Gulf, including Kuwait, there are more dusty days compared to the southern part [5]. In Kuwait, the mean total annual dusty days is 255 days which definitely will act as a challenge for solar power generation in the region. Therefore, place Kuwait as an ideal location for investigating the significant effect of dust and weather challenges on the generation of solar and wind energy generation. The aim of this study is to determine the potential feasibility of setting up solar and/or wind energy systems in Kuwait focusing on the environmental challenges. This study covers successful control measures that were applied to control or minimize the effect of such challenges.

2 Methodology

2.1 The depositional dust rates and weather data

In Kuwait, humidity and average solar radiation data (2010-2016) were attained from 9 weather stations. The solar radiation was measured via the Li-COR

pyranometer fixed at a 10-meter above ground level in all weather stations.

Fallen dust amounts were monitored for two years (September 2009 – August 2011) from 47 locations in Kuwait using dust collectors following Reheis (1995) design that was (Figure 1). The trap is 240 cm in height and with a 20 cm radius from ground level (Figure 2). The deposited dust was collected every month from all traps.

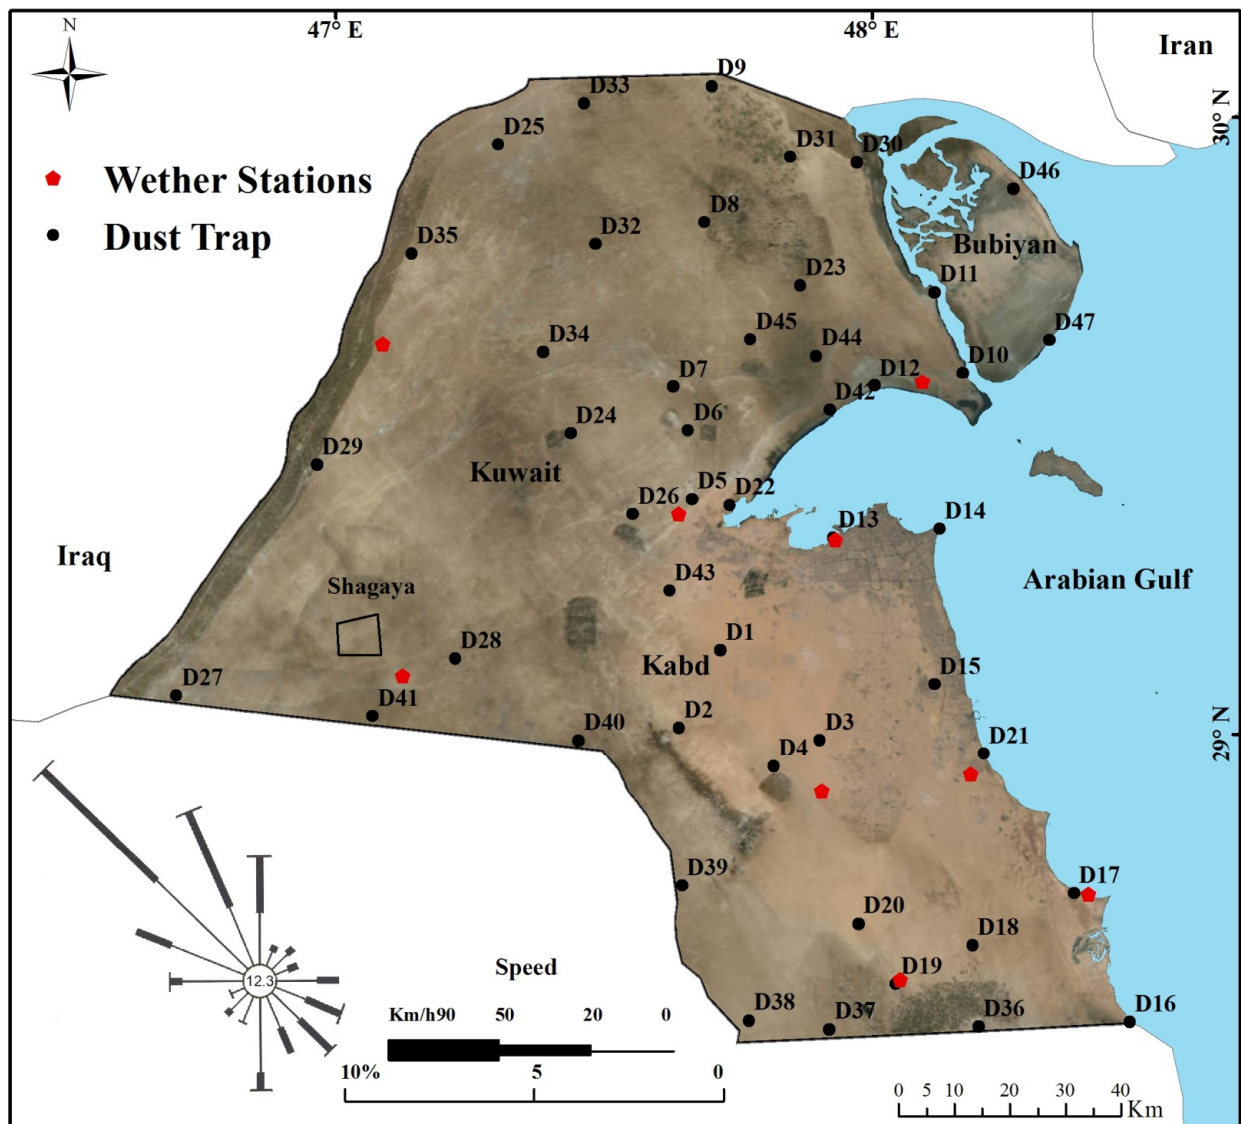

Fig. 1. Location map for the weather (1958-2016) and dust (2009-2011) monitoring stations with the average wind rose for Kuwait and showing the Shagaya area.

The wind and solar energy power plants with 10MW capacity each, located in the Shagaya area west of Kuwait were compared (Figure 3). The wind is represented by five wind turbines (2 MW for each) that were fixed near the photovoltaic energy unit. The wind and PV farms were studied from an economic point of view with reference to their Levelized Cost of Electricity. The monthly capacity factor was calculated for a one-year operation (June 2017 to July 2018). Annual production of both plants was measured; Capital Expenditure and operation expenditure were taken into

concern throughout the life of the plants together with Investment costs.

2.2 Carbonates and Mud in dust

Dust fallout particle size percentages were identified via sieve mesh (63 micrometers) to separate sand from mud for all samples for four months (November, August, May and February 2010). Also, the carbonates (mainly calcite and dolomite) within collected dust samples during

March, June, September, and December were identified using Philips PW-1830 X-ray diffraction (XRD).

Fig. 2. The dust trap (left photo) and diagram (right sketches).

Fig. 3. Dusty solar panels compared to cleaned panels at the KISR.

2.3 Mapping

The collected data for depositional dust rates, mud and carbonates percentages, humidity, solar radiations, and wind were stored as layers using the ArcGIS S/W software, and geostatistical interpolator (Simple IDW method) was steered to create the annual average distribution maps.

Approximately 110 thousand native plants

(*Haloxylon salicornicum*, *Lycium shawii*, *Nitraria retusa*, and *Calligonum polygonoides*) were planted at a 3-m average distance between plants in highly degraded land with no vegetation. Both five sand and dust traps were fixed (2 at 100 m downwind, 2 at 100 m upwind, and 1 in control area) for monitoring the aeolian deposition (dust and mobile sand) monthly for four years (September 2011–August 2015).

3 Results and Discussion

The annual dust deposition rates are 149-576 t km⁻² (average is 339 t km⁻²) in 2010-2011 and 10-1065 t km⁻² (average is 216 t km⁻²) in 2009-2010. The average dust rate maps were delineated based on the average annual dust deposition in two years 2009-2010 (Fig. 4a) and 2010-2011 (Fig. 4b). These maps show momentous trends in dust accumulation over the two years of monitoring. The maps classify specific spaces with high (more than 350 t km⁻²) and low dust deposition in the two years, but the spaces with high dust deposition extend to cover more places in 2010-2011 compared to 2009-2010. This will surely will affect solar energy in Kuwait and the surrounding regions. The effect of dust on solar or wind energy production was globally and regionally addressed by many researchers.

The deposition of dust on surfaces of photovoltaic cells can increase cleaning cost which is considered necessary to ensure the minimization of efficient operation and power leakage. Dust deposits on photovoltaic cells, combined with a lack of water sources in the desert regions to clean the solar-power system will add a variable cost for cleaning services. Dust can have a damaging effect on the operating potential of photovoltaic plants. Dust was revealed to degrade the energy delivery, which in turn causes a decrease in the energy output of photovoltaic cells by 15% to 30% [15]. Power fall can even reach 100% during humid periods with dust concentration by water-soluble salts.

3.1 The mud content

The mud is particles that are less than 4 phi (0.063 mm) in size diameter. Mud contains two major size fractions; these are silt and clay. It was noted that the southern areas in Kuwait contain fewer mud percentages compared to northern Kuwait. Deposited dust during February revealed the lowest mud ratios when compared to other months, while November and August revealed the highest. The annual mud percentages present in accumulated dust range from 10-95%, with 63% as an average (Fig. 4c). Globally, the mud highest percentages (≥ 85%) within dust are recorded in Cairo – Egypt, Um Qasir – Iraq, Manamah – Bahrain, Cartagena – Colombia, and Bald Hill – Australia.

3.2 The carbonates content

Carbonates and quartz form the main constituent of dust mineralogy in Kuwait (Table 1).

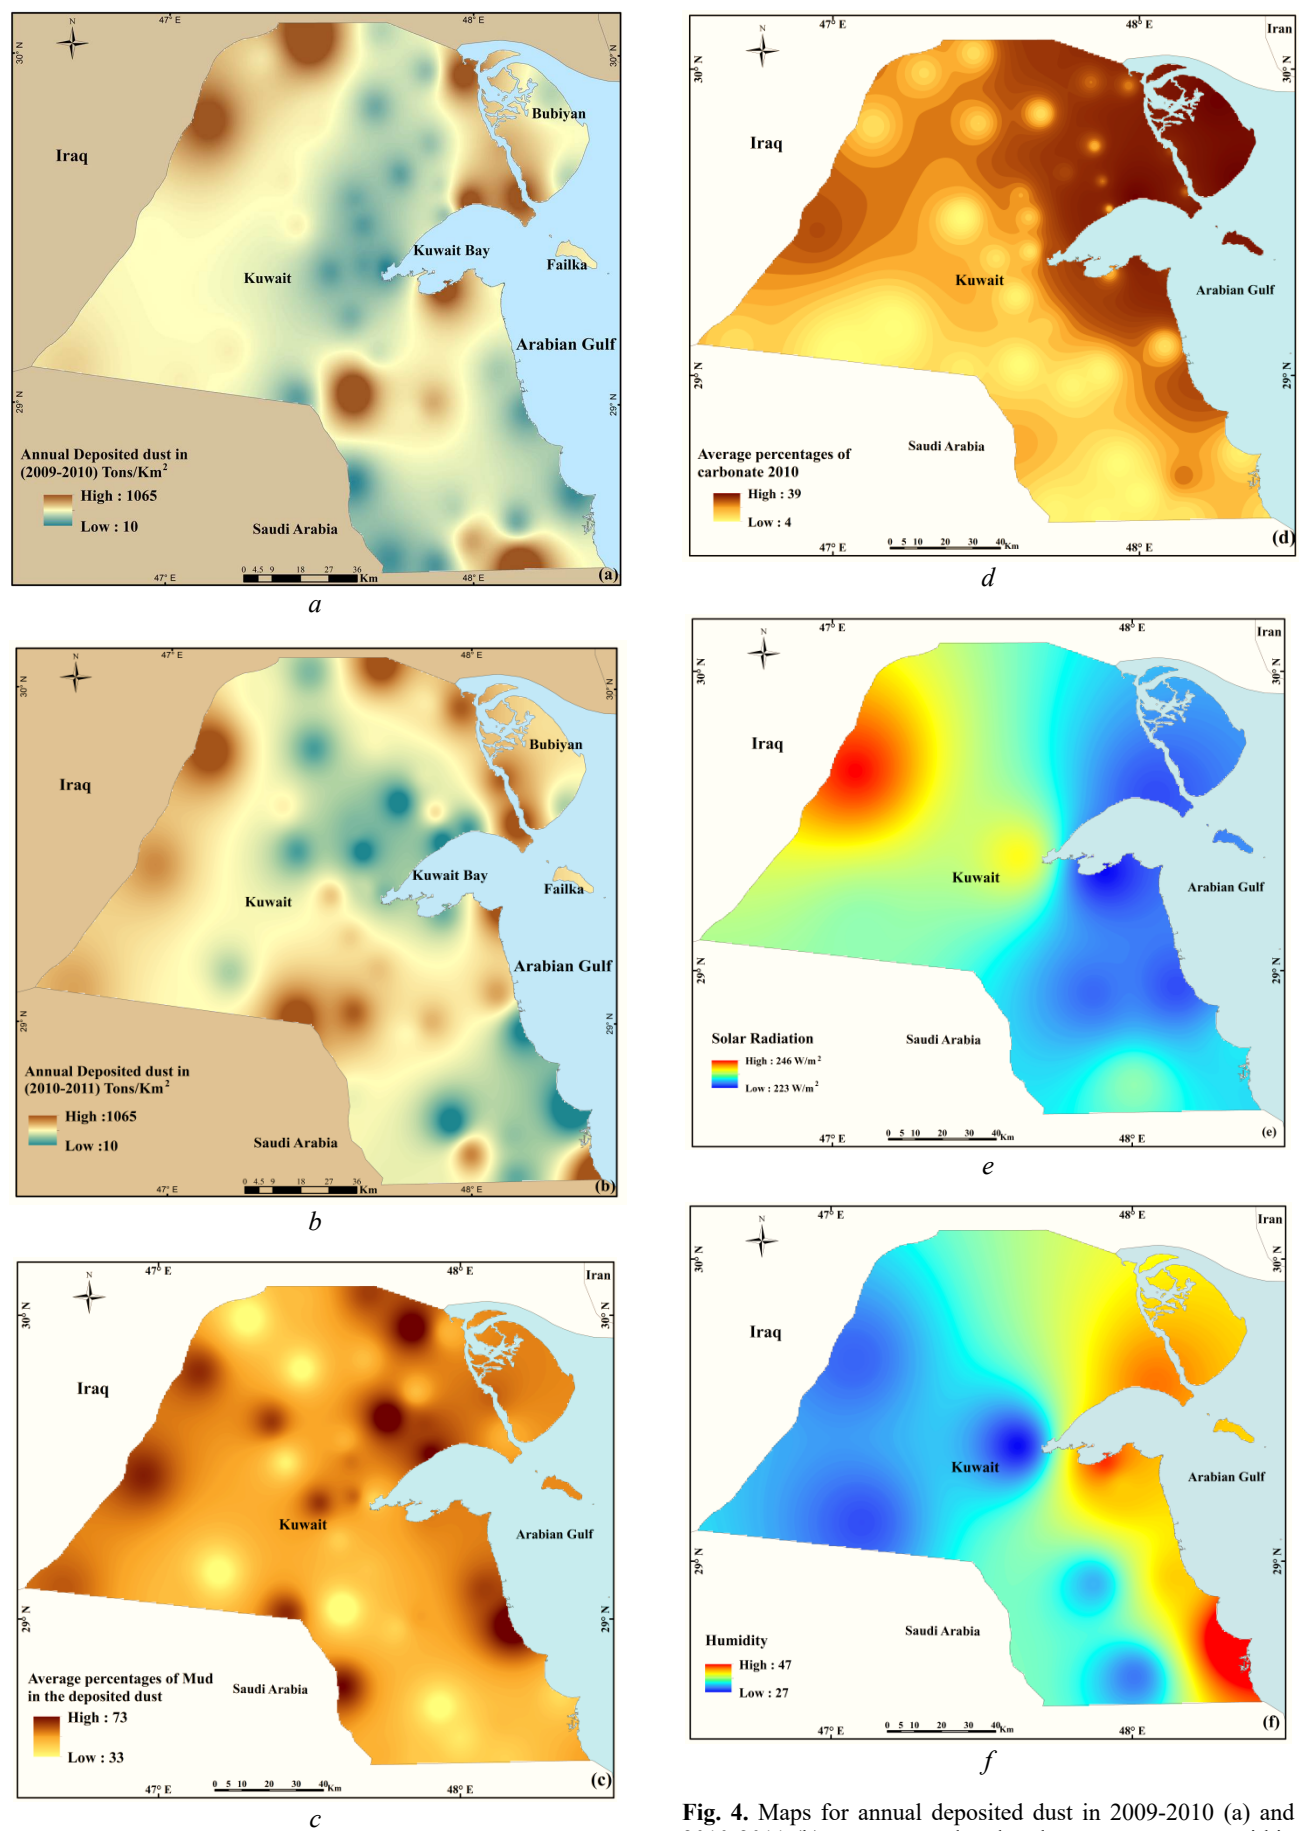

Fig. 4. Maps for annual deposited dust in 2009-2010 (a) and 2010-2011 (b), average mud and carbonate percentages within dust (c, d), and average solar radiation and humidity (e, f).

Table 1. The mineralogical percentages and average particle size of dust in Kuwait compared to global dust samples.

Location	Particle size %		Minerals %				
	Sand	Mud	Carbo-nates	Qu-artz	Feld-spars	Clay	Others
Kuwait	37	63	45	38	10	2	5
Ain – Emirates	97	4	52	26	20	1	0
Dubai – Emirates	17	82	45	21	6	0	27
Ahwar – Iraq	3	97	80	13	8	0	0
Manama – Bahrain	12	87	41	32	10	3	15
Walameen – Saudi Arabia	40	61	13	62	24	1	0
Amman – Jordan	30	70	68	21	4	0	7
Tripoli – Libya	20	81	27	64	5	4	0
Biougra – Morocco	12	88	46	46	8	1	0
Cartagena – Colombia	10	90	0	66	33	0	1
Bald Hill – Australia	9	90	0	57	21	14	7
Cairo – Egypt	10	90	34	51	15	0	0
Average	25	75	38	41	14	2	5
Maximum	97	97	80	66	33	14	27

The dust contains higher carbonate percentages during October-April reaching up to 58%. The presence of higher carbonate percentages acts as a good indication for low aeolian activity during summer (May-September). The northwestern and western areas show the lowest percentages down to 5% of the total mass of dust. The average annual carbonate percentages within the deposited dust range from 4 to 36.8% with 27.6% as average (Fig. 4d). The highest carbonate percentages are in the northeastern parts of Kuwait and coastal areas. Kuwait, Bahrain, and Dubai contain nearly similar amounts of carbonates in dust samples. On the other hand, carbonates vary a lot in other regional areas such as Al-Ahwar and Um Qasir – Iraq (Table 1). This is attributed to the dust storms that originate from Iran and Iraq is rich in mud and carbonates [7].

3.3 The solar radiation

The average annual solar radiations on the horizontal surfaces in Kuwait are represented geographically (Fig. 4e). The average annual solar radiation ranges from 223 Wm⁻² to 246 Wm⁻² which is so low. The northwestern and north areas in Kuwait reveal higher solar radiation compared to other areas.

The average humidity similar to solar radiation, coastal areas show higher percentages while other areas show lower humidity percentages (Fig. 4f). The carbonates and/or mud mixed with humidity causing the development of a thin-crust layer on solar panels that are difficult to clean. Numerous cleaning can effect, scratch and damage to solar panels.

3.4 Solar photovoltaic (PV) and wind energy

After one year of operation at photovoltaic units and wind turbines in Kuwait, the outcomes show that wind turbines record production energy numbers that go beyond the production average. This was connected with high capacity factors during one year, consequential in an annual power production that is 2.3 times greater than that of solar panels; running 450 homes compared to 199 homes for PV (Figure 5, Table 2).

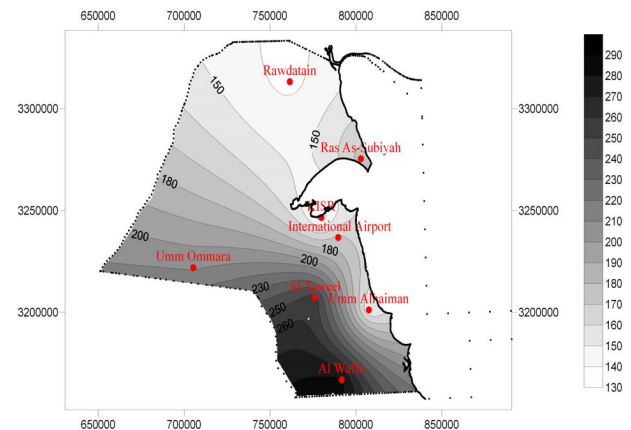

Fig. 5. A map for wind power density W/m² distribution over Kuwait at a height of 30 m (top) and the wind turbines in the Shagaya area at western Kuwait (bottom).

Similar to solar radiation, coastal areas show higher percentages while other areas show lower humidity percentages (Fig. 4f). The carbonates and/or mud mixed with humidity causing the development of a thin-crust layer on solar panels that are difficult to clean. Numerous cleaning can effect, scratch and damage to solar panels.

Table 2. The Shagaya Wind and PV Farms economic results.

	Wind Farm	PV Plant

4 Conclusions

The Arabian Gulf governments recently proposed a strategy for the expansion in using sustainable energy mainly photovoltaic energy with a more ambitious vision to act as a solar and wind energy exporter. This study has positively identified the surrounded challenges that can disturb the performance of photovoltaic technologies in the desert region. On the other hand, the development of photovoltaic energy units in Kuwait and the Gulf countries should take into concern environmental challenges, such as fallen dust, and mud, carbonates, humidity, and solar radiation. The effect of dust (depositional rates, mud and carbonate contents), solar radiation and humidity on the power efficiency of photovoltaic panels were observed. Therefore, wind as an alternative source of energy would be more feasible. The Bubiyan Island, southwestern and western sides of the state of Kuwait and southern are the potential sites for wind farm establishment. Several control measures including the establishment of green belts and plantation of native shrubs were found proper in reducing dust by 64.5% and 68.4, respectively.

This project was funded by the KFAS (Kuwait Foundation for the Advancement of Science) and KISR (Kuwait Institute for Scientific Research) grant number (2008,1401,01). Thanks are extended to National Meteorological Network at KISR for their support with meteorological data.

Optimization of air chamber in solar air collector

Orest Pakholiuk*, Iryna Zadorozhnikova, Serhii Uzhehov, Oleksandr Chapyuk, and Ruslan Pasichnyk

Lutsk National Technical University, Lutsk, Ukraine

Abstract. Recently, environmental problems have become more acute. In 1980, the International Union for the Conservation of Nature (IUCN) prepared the World Conservation Strategy. This document interpreted the term “sustainable development” as an inseparable link between social development and nature conservation. And already in 1992, after the United Nations Conference on Environment and Development, the concept of sustainable development gained a leading status. The conference materials determined that sustainable development is a development of a society that meets the needs of today without compromising the ability of future generations to meet their own needs. Therefore, being aware of the need for energy conservation, there is increasing emphasis on the use of solar energy throughout the world to generate electricity and heat.

1 Introduction

The potential of solar energy in Ukraine is sufficiently high for widespread use both heat-and-power engineering and photovoltaic systems in almost all regions. The period of functional operation of solar heating systems in the southern regions of Ukraine is 7 months (from April till October), in the northern regions it is 5 months (from May till September). Photovoltaic equipment can be used very effectively throughout the year [1, 2].

For solar heating in climate weather conditions of Ukraine, the exploitation of flat solar collectors that use both direct and diffuse solar radiation is effective. Concentrating solar collectors can be quite effective only in the southern regions of Ukraine.

The use of renewable source of energy in Ukraine and in the world is gaining momentum. Solar collectors are increasingly popular. However, prefabricated collectors are quite expensive and their payback period is significant. Therefore, many engineers are working on simple and lowcost designs.

Solar collectors are a number of devices with some differences in types, shape, types and purpose. There are two main types of solar collectors as liquid and air. Solar air collectors are often plain flat collectors.

The main advantages of air collectors are their simplicity and reliability. Such collectors have a simple structure. With proper care, a quality collector can work for 10-20 years, and it is very easy to manage. The heat exchanger is not needed because the air does not freeze.

On Fig. 1. shows a map of solar radiation power on horizontal surfaces within Ukraine. In the Eastern and Southern regions, solar installations will be significantly more efficient.

A potential way to reduce the cost of collectors is their integration into walls or roofs of buildings, as well as the

creation of collectors that can be assembled from prefabricated components.

Fig. 1. Global Horizontal Irradiation for Ukraine (The World Bank, Solar resource data: Solargis, 2017).

These collectors are often used for heating. However, the opportunity to get cheap thermal energy in the summer has led to a wide range of applications of such installations for drying agricultural products. Therefore, research in this direction continues to these days [3-7].

The benefits of solar air collector:

1. Additional protection of facade (roof) materials from ultraviolet radiation.
2. Installation of skewed canopy (porch, parking space) while receiving house solar heating with solar collector is possible.
3. Saving energy. Cleaning air circulation. Highly efficient heating.

Today the most common are the following designs of available air solar collectors: with the movement of the air through the air chambers of various forms (Fig. 2), with the movement of the air in the space between the bottom of the case and solid screen absorber (Fig. 3), and with the movement of the air between the glass and bottom absorber on a fixed path (Fig. 4).

Fig. 2. Collector with the air passing through air chambers: 1 – air chamber; 2 – glass; 3 – baffle; 4 – body; 5 – insulation; 6 – air outlet; 7 – air intake.

Fig. 3. Collector with the air passing between the bottom of the case and solid screen absorber: 1 – absorber; 2 – glass; 3 – body; 4 – insulation; 5 – air outlet; 6 – air intake.

Fig. 4. Collector with the air passing between the glass and bottom absorber on a fixed path: 1 – air intake; 2 – baffle; 3 – body; 4 – air outlet; 5 – absorber.

Air passes through the absorber due to natural convection or under the influence of a fan. Since air conducts heat worse than liquid, it receives less heat from the absorber than the liquid coolant. In some solar air heaters, fans are attached to the absorber, which provide air passage and improve heat transfer. The disadvantage of this construction is that it consumes energy to operate the fans, thus increasing the cost of the system operating. However, the use of solar panels to power the fan, eliminate this disadvantage. In cold climates, the air is directed to the gap between the absorber plate and the insulated rear wall of the collector: thus avoiding heat loss through transparent surfaces.

Solar air collectors are simple devices, however have a numerous of options of constructive execution, warming, a material and a covering of an absorber, a translucent covering, and means of ensuring creation of turbulent air streams inside. Therefore, a large number of

scientific studies of various authors is devoted to the study of their properties and design features [8-11, 16-19].

Proper orientation of solar collectors (direction and angle) increases their productivity. The earth's atmosphere absorbs and reflects a significant portion of solar energy. Therefore, the maximum amount of energy comes at noon, when the direct rays' stream is least delayed by the atmosphere. In the northern hemisphere geographical south is the best direction at noon, while the sun's rays strike perpendicularly upon the collector. A simple geometric calculation shows that the collector should be inclined to the horizon on the value of the latitude of ± 10 angular degrees. For example, in Kyiv, $50^\circ 25'$ north latitude, which means that the angle can be 40 to 60 angle degrees [12-15].

Azimuth characterizes the deviation of the collector surface from the south; at the orientation of the collector surface straight to the south, the azimuth = 0 . Since the insolation in the middle of the day is the most intense, the collector surface should be oriented to the south as far as possible. However, good results are also achieved by the deviations from the south in 45° to the southwest or southeast. More significant deviations can be compensated by a small increase in the surface area of the collector.

2 Methods

2.1 Investigation of air chamber's properties in solar air collectors

Taking into account the most predictable movement of the coolant inside collectors with the movement of the air through air chambers, we shall undertake a study on the efficiency of chamber forms to outline the optimized and the most effective alternative.

The principal condition of providing effective operation of the solar air collector is the maximum coverage of the air chamber walls by the airflow to relieve them from the heat. It can be achieved by creating turbulent flow. The easiest way is to arrange bafflers along the channel, which can provide the turbulence.

In order to get that done, a comprehensive research on the study of the potential of the channels with different types of bafflers.

Prototypes were made of thin-walled cylinder with a smooth inner surface. The 4 section cylinders were secured to the window glass on one level separately from each other, so as not to block the sun's access to the surfaces. Thin-walled aluminum cylindrical tube with a diameter of 70 mm, the wall thickness of $0,1$ mm, and 170 mm long section between delimiters, was used as the channel. The tube was covered with CRAFTS SPRAY HighTemperature black paint to improve the perception of solar radiation. Research samples consisted of 4 sections were created for all types of bafflers. All samples were fixed in an identical lighting conditions, the temperature was measured both at the inlet and outlet of the channel with different measurements for each channel in the $20^\circ \dots 30^\circ$ C.

The second part of the experiment was mathematical modeling of the air passing through the bafflers to visualize the trajectories of the motion of the fluence.

It is flexible enough to check various situations, and it is a good instrument to prepare physical tests, its verification or confirmation.

One of software packages of this kind is SolidWorks, a program complex for the complete 3D modeling with Flow Simulation program unit, which provides opportunities to create the most complex three-dimensional parametric objects and dipping them into certain environment, defining necessary parameters and characteristics, as well as obtaining an animated image of the flow process which is saved as AVI-file.

2.2 Research methodology

Four-sectional samples were fixed to the window glass on one level apart from each other to keep the access to sunlight surfaces.

The principal scheme of the holes in the baffler are shown in Fig. 5. The holes in the bafflers on Schemes 3...9 were made open-ended, changing only the configuration. Openings in the bafflers on Schemes 1...2 were made by fat contour line, then the dimmed plane was bent inwards at an angle of 45°.

Fig. 5. The principal schemes of the holes in bafflers.

At the junction of sections, each subsequent baffler was turned on an axis at an angle of 90° from the previous for the turbulence of the flow.

Temperature measurements were carried out at the intake of an air flow in the prototype and at the outlet at different lighting levels in the winter and spring periods. Thermo Clock electric thermometer with internal and external (as thermocouple) temperature sensors was used for measurements. Temperature measurements were performed twice:

1st measurement: the temperature at the intake was measured with thermocouple;

2d measurement: the temperature at the intake was measured with the thermometer's internal sensor, and at the outlet it was measured with thermocouple.

Temperature measurements were carried out at different lighting levels, which were metered with luxmeter.

Fig. 6. A scheme for determining the effectiveness of the samples: 1 – baffler; 2 – tube sections; 3 – mounting; 4 – electric thermometer; 5 – thermocouple.

3 Results and discussion

3.1 Efficiency of channels in the field experiment

The results of studies at different levels of illumination are summarized in Table 1.

Table 1. The temperature at the intake and outlet of the samples at different light levels

Row Nr.	T _{outside}	Temperature at the outlet of the sample T							
		1	2	3	4	5	6	7	8
1	6,0	13,3	12,7	12,5	13	12,8	12,6	13	13,1
2	7,0	15,6	15	14,9	15,4	15,1	15	15	15,4
3	14,5	19,2	16,1	14,5	16,5	14,6	14,5	14,5	17
4	17	43,6	40,1	34	36	38,5	39,5	45,5	38
5	18,6	27,5	28	25	27,3	27,8	26,3	26,8	27,5
6	25,0	46,9	44,4	44,3	45,3	44,8	41,2	50	47,1

Considering that at the time of the study there was a constant cloudiness, the increase in solar radiation led not only to an increase in the outside temperature, but also to an improvement of the heat transfer by the collector elements.

The data of Table 1 are shown on chart (Fig. 7).

With the efficiency of the channel dividers, the difference between the inlet and outlet air flow temperatures is accepted. The results of studies at different levels of illumination are summarized in Table 2.

The results of the experimentation have shown that the most effective was sample Nr. 1, sample Nr. 7 had very

close value to the first one, and samples Nr. 8 and Nr. 2 were in the third place.

Fig. 7. Temperature distribution in the samples.

Table 2. Effectiveness of chamber bafflers.

Row Nr.	Difference between inlet and outlet temperatures of air flow							
	1	2	3	4	5	6	7	8
1	7,3	6,7	6,5	7	6,8	6,6	7	7,1
2	8,6	8	7,9	8,4	8,1	8	8	8,4
3	4,7	1,6	0	2	0,1	0	0	2,5
4	26,6	23,1	17	19	21,5	22,5	28,5	21
5	8,9	9,4	6,4	8,7	9,2	7,7	8,2	8,9
6	21,9	19,4	19,3	20,3	19,8	16,2	25	22,1
Average	13,0	11,37	9,52	10,9	10,92	10,17	12,78	11,67

We take the effectiveness of the sample Nr. 1 as 100%. Experimental samples in Table 3 are shown in the order of increasing.

Table 3. Experimental samples in the order of increasing of the effectiveness.

Sample Nr.	3	6	4	5	2	8	7	1
Comparative effectiveness	73,21	78,21	83,85	83,97	87,44	89,74	98,33	100

3.2 Channel efficiency in mathematical modeling

To visualize the trajectories of the fluence motion, in the second part of the experiment, Mathematical modeling of air passing through the bafflers was carried out with the aid of SolidWorks program complex with FlowSimulation program unit. The results of modeling are shown on Fig. 8-16.

Mathematical modeling has shown that bafflers of samples Nr. 1, 2 and 7 have the best performance of blowing the chamber walls.

The efficiency of the channel dividers modeled in SolidWorks was determined by the nature of the airflow trajectory after passing them separator.

4 Conclusions

Passing through the channel, the air changes its state. This is due to the differential heating of absorber surface by the sun, and owing to the bafflers that divide the channel into identical pieces. The baffle's shape influences the flow pattern in the air chamber.

The results of the multiple use of air chamber samples of solar collectors with bafflers have shown that samples Nr. 1, 2 and 7 are the best for the use, which we suggest to use for making solar collectors.

Abstract. The use of renewable energy in sustainable tourism development of the region is substantiated in the paper. There are three stages in selecting areas for projects on renewable energy sources: selection of the potentially suitable area; consideration of exclusion criteria; detailed assessment of potential areas. The impact factors on spatial constraints and the opportunities for building solar power plants, on the parameters of sustainable tourism development in the Carpathian region were determined. New research findings were obtained, the result of which was the concept and cartographic models of the environmentally safe location of renewable energy objects. New methods and methodological recommendations for the development of renewable energy in the Carpathian region were described as prospective taking into account the constraints on the parameters of environmental safety and tourist use of the territory.

1 Introduction

It is known that in Ukraine, as well as in many countries in the world, there is the need for alternative energy due to the lack of conventional energy sources. At present, it is believed that the use of renewable energy sources is one of the ways to solve this problem. The relevance of the scientific project is apparent and is related to the fact that the world community regards the use of alternative and renewable energy as one of the most promising solutions to the growing problems of energy supply. Solar energy is one of the most promising alternative sources of energy. Considering the dynamics of reducing the cost of electricity, generated by the sun, it is strategically important for Ukraine to develop these directions in the future, especially in such a difficult economic situation.

Many works are devoted to the efficiency and expediency of the use of solar energy [1, 2]. Substantial results are obtained in the Institute of Semiconductors Physics of NAS of Ukraine, in the Kyiv, Odesa, Uzhhorod and Chernivtsi Universities, on some industrial enterprises (“Pillar”, “Quasar”), in other Ukrainian laboratories.

All of them state, that the use of alternative energy sources in Ukraine, mainly solar energy, will undoubtedly bring benefits [3].

The prospects of introducing renewable energy sources should be considered in the light of trends in tourism potential, represented by the number of historical, cultural and natural resources, as well as the level of tourism infrastructure development, which mainly

depends on the available number of catering establishments and accommodation.

In general, the current state of analysis and assessment of solar energy sources is considered in the article. The main types of works concerning the natural resources of renewable energy, the scientific achievements related to the use of natural resources for the development of alternative energy, which contain a general and special description of renewable energy resources, ways of their use and evaluation have been singled out and analyzed. The conducted analysis has shown that today more and more authors devote their works to the systematization and improvement of non-traditional energy sources and complex calculation of the options, by means of which energy can be obtained [4-6].

Very often, the necessary data on solar energy are absent, and for this purpose the analytical dependencies are used, which help to solve the set tasks with sufficient accuracy.

Another source of sun radiation of a certain territory is the results of long-term NASA research, including satellite measurement, atmospheric design, and surface studies. In this model, such factors as climatic zones, reflectance, turbidity, precipitation, and aerosols in the atmosphere are used in atmospheric design [7].

Renewable energy sources help to solve the problem of the sustainable development of mankind by reducing air, water and soil pollution, but they can also have an environmental impact.

In addition to favorable climatic characteristics, spatial planning of the area with environmental

* Corresponding author: moskalcuknatalia@gmail.com

constraints is important, as it can help to avoid the obstacles to planned activities, environmental impact or public dissatisfaction.

2 Problem statement

The purpose of the paper is to substantiate the feasibility of introducing solar energy resources in the Carpathian region and to prove that there are no objective resource obstacles to the development of solar energy in the Carpathian region. Recently, there has been a growing interest in using photovoltaic panels to produce electricity by converting solar energy.

Along with other renewable energy devices, the photovoltaic panels have several advantages, including the simplicity of design and structure, light weight and dimensions, and long life. However, their main disadvantages are their low efficiency, the instability of electricity due to weather conditions and the dependence of output power on the incidence angle of sunlight on the absorbing panel. To use solar installations, it is necessary to have data on the distribution of solar radiation in the area. The administrative Carpathian region includes Ivano-Frankivsk, Lviv, Zakarpattia and Chernivtsi oblasts.

There arises the need to assess the tourist potential of the territories. In this regard, it is necessary to develop a model of tourism organization in the region and identify the territories that require priority concentration of efforts and resources for their development, protected areas and territories where tourism infrastructure is inappropriate [8].

Thus, there is a need to solve the following tasks: to accumulate the data on solar radiation intensity in each tourist region; to process the data and determine probable characteristics of the intensity of solar radiation distribution [9,10].

The introduction of new facilities, including solar power plants, requires a complex of pre-investment research, which should include the environmental impact assessment in addition to assessing the energy potential. The environmental impact assessment is usually carried out in three stages:

1. determination of first-line impacts (screening);
2. development of a complex of mitigation measures;
3. impact significance assessment;
4. decision making.

The notion of “impact significance” is a core concept of the Directive 2011/92/EU “On the assessment of the effects of certain public and private projects on the environment” [11], which was introduced in the Ukrainian legislation in December 2017 by the Law of Ukraine “On Environmental Impact Assessment” (EIA) [12]. Article 3 of the Directive requires that “the environmental impact assessment shall identify, describe and assess in an appropriate manner, in the light of each individual case” [11]. For this reason, it is necessary to justify the impact significance assessment, in particular it is important to establish a transparent methodology that explains the approaches of assessment and its practical application.

The impact significance assessment should not be the exclusive prerogative of professionals: the significance should be determined in such a way as to reflect what is assessed in the environment for the authorities and the public. A common approach used in EIA is a multi-criteria analysis [13]. The multi-criteria comparative analysis, which uses different methods, makes it possible to assess the significance, when it cannot be done using standard absolute methods, and to compare different impacts.

3 Results and discussion

3.1 Method of determining the prospects of the oblasts of the Carpathian region for the implementation of renewable energy sources

The Carpathian region development strategy is the tourism industry. At present, the development of tourism industry requires an ecologically-oriented attitude to natural resources and their use.

Having analyzed the available methods for assessing the tourism potential [14, 15], we propose our own point assessment, based on the integrated ranking of the territories. We propose to introduce an appropriate assessment of tourism potential in accordance with the integrated rating of individual oblasts of the Carpathian region on a scale (1-1.7 – low; 1.8-3.3 – medium; 3.4-5.0 – high) for each area, based on a maximum score of 5 points.

The components of tourism potential are the amount of historical and cultural resources (K_{hc}), natural resources (K_n) and the main components of tourism infrastructure (K_{inf}) – accommodation and catering establishments.

Taking into account the number of these units in the oblasts of the region, we introduce a degree of ranking (R) of historical, cultural, natural resources and infrastructure – $R_{K_{hc}}$, R_{K_n} , $R_{K_{inf}}$, respectively.

For each of these components, we set the coefficients of significance (S), respectively:

$$S_{K_{hc}} = 0,3, S_{K_n} = 0,3, S_{K_{inf}}$$

The integral rank for each region is determined by the sum of the products of the degree of ranking and the importance of each component in Equation 1:

$$I = R_{K_{hc}} * S_{K_{hc}} + R_{K_n} * S_{K_n} + R_{K_{inf}} * S_{K_{inf}} \quad (1)$$

Based on the maximum score of 5 points, we determine the point estimate of the tourist potential by the integrated ranking according to the scale:

- 1-1.7 – low;
- 1.8-3.3 – medium
- 3.4-5.0 – high.

According to the point evaluation of the tourist potential, we have determined the levels of prospects of the oblasts for introducing renewable energy sources in tourist complexes in each of the oblasts of the Carpathian region (Figure 1).

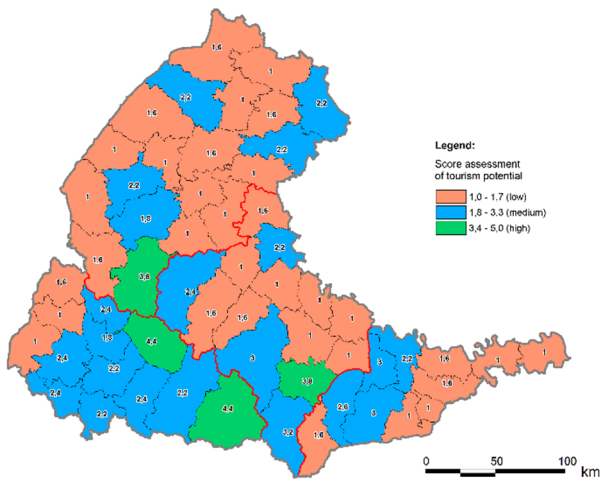

Fig. 1. Estimation of tourist potential by the integrated ranking of individual oblasts of the Carpathian region of Ukraine.

In Ivano-Frankivsk oblast the highest level of prospects can be expected in Kosiv region; medium – in Verkhovyna, Halych, Dolyna, Nadvina, Yaremche regions, Ivano-Frankivsk; low – in Bohorodchany, Horodenka, Kalush, Kolomyia, Rohatyn, Rozhnativ, Sniatyn, Tysmenytsia, Tlumach regions.

In the case of Lviv oblast, the highest level of prospects can be expected in Skole region and the outskirts of Lviv; medium – in Brody, Drohobych, Zhovkva, Zolochiv, Sambir regions; low – in Buh, Horodok, Zhydachiv, Kamianka-Buzka, Mykolaiv, Mostysky, Peremyshliany, Pustomytiv, Radekhiv, Sokal, Starosambir, Stryi, Turkiv and Yavoriv regions.

In Zakarpattia oblast the highest level of prospects is in Mizhhirria and Rakhiv regions; medium – in Berehovo, Vynohradiv, Volovetsk, Irshava, Mukachevo, Svaliava, Tiachiv, Khust regions; low – in Velyki Berezniany, Perechyn and Uzhhorod regions.

In Chernivtsi oblast the highest level of prospects are on the outskirts of Chernivtsi; medium – in Vyzhnytsia, Zastavna, Kitsman, Storozhynets regions; low – in Hertsaiv, Hlybochytisia, Kelmintsi, Novoselytsia, Putyvl, Sokyriany and Khotyn regions.

3.2 Method of determining the prospects of the oblasts of the Carpathian region for the implementation of renewable energy sources

Having identified which areas are promising in terms of tourism industry development, we can envisage the appropriate scenarios for the introduction of renewable energy sources, attracting internal and external investments in tourism activities related to the sphere of the economic complex of the region. The regional average annual values of the total solar radiation within the whole Carpathian region on the horizontal (underlying) surface are presented on the Map Info map, that we developed in GIS, in Figure 2, containing 10 color gradations. The results indicate a gradual decrease in the quantitative indicators in the direction of the south-east-northwest.

The efficiency of light-absorbing panels operation in the Carpathian region has been studied on the basis of the

Ivano-Frankivsk National Technical University of Oil and Gas since April 2015. Daily measurements of electricity produced and meteorological indices are carried out.

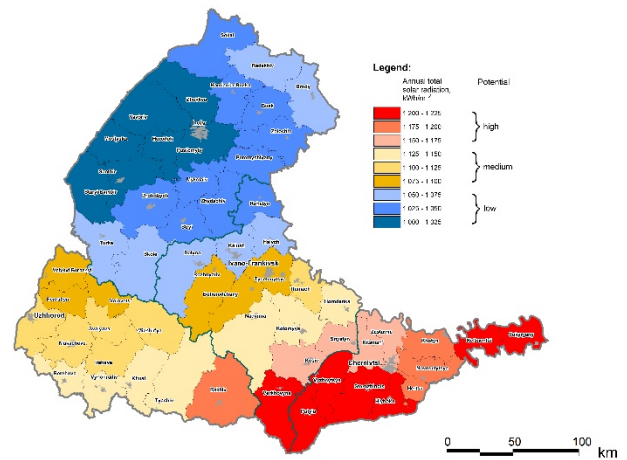

Fig. 2. Annual total solar radiation in the Carpathian region of Ukraine.

The experimental study has been conducted; the obtained results have been statistically processed. The functional dependence of generating electricity on meteorological parameters has been identified, namely, cloudiness, probability of precipitation, air temperature, atmospheric pressure, humidity and wind speed.

According to the results, the amount of obtained energy substantially depends on the indexes of cloudiness (Figure 3), humidity (Figure 4), and air temperature (Figure 5).

Fig. 3. Functional dependency of electricity generation by the photovoltaic panels on the level of cloudiness in Ivano-Frankivsk.

Functional dependencies were established by processing long-term observation data using TableCurve 2D software. The program uses the basic criteria of statistics: the sum of squares of the mean, sum of squares of errors (residuals), degree of freedom calculated depending on the number of model parameters, standard error, coefficient of determination (r^2), coefficient of determination adjusted for the degree of freedom (DF r^2), and F-statistics (Fisher test).

Fig. 4. Functional dependency of electricity generation by the photovoltaic panels on the level of humidity in Ivano-Frankivsk.

Fig. 5. Functional dependency of electricity generation by the photovoltaic panels on the air temperature in Ivano-Frankivsk.

The values of the coefficient of determination were estimated using the F-distribution quantile tables and the tables of values of coefficients. The critical values of the Fisher test were defined according to standard tables. The hypothesis (existence of a close dependence) was rejected if the value found in the table (Fstat) was greater than the calculated (Fstatm), and was accepted as the one that was confirmed if $F_{stat} < F_{statm}$. In three cases (Figures 3, 4, 5), the hypothesis was confirmed, provided that the significance level was accepted at 1%.

However, there is no direct correlation between the indices of atmospheric pressure and wind speed. In two cases (Figures 6, 7) the hypothesis was rejected, provided that the significance level was accepted at the level of 1%. The critical values of the Fisher test corresponded to standard tables. The hypothesis (existence of close dependence) was rejected because the value found in the table (Fstat) was larger than the calculated one (Fstatm).

Fig. 6. Results of processing the experimental data of measurements of electricity production by photovoltaic panels and wind speed in Ivano-Frankivsk.

Fig. 7. Results of processing the experimental data of measurements of electricity production by photovoltaic panels and atmospheric pressure in Ivano-Frankivsk.

Therefore, based on the obtained experimental data and statistical meteorological data, the dependency curves of electricity production with the help of a light-absorbing panel on weather conditions were developed, which made it possible to perform forecast calculations.

The scientific novelty of the performed research is that we obtained significant functional dependencies of electricity production by means of a light-absorbing panel on the air temperature, cloudiness, relative humidity for local conditions of Ivano-Frankivsk oblast.

3.3 Method for environmental impact significance assessment of renewable energy

The suggested method for environmental impact significance assessment is based on the requirements of the national legislation for the components of the Environmental Impact Assessment report [12], the recommendations of the EU guidelines on Environmental Impact Assessment [13, 16], national guidelines on the implementation of the Strategic Environmental Assessment (SEA) [17], data of the Strategic Environmental Review conducted by Ukraine Sustainable Energy Lending Facility (USELF) [18]. In particular, the SEA guidelines recommend using a methodological approach to significance assessment that is based on the evaluation of all identified impacts by uniform qualitative and quantitative criteria that reflect the magnitude of impact (including intensity, spatial and temporal coverage, reversibility, probability of occurrence) sensitivity of the recipient.

The proposed method concerns the impact of the significance assessment of renewable energy, in particular solar power plants, on the environment and is carried out after screening and mitigation measures.

Due to the fact that many factors impacting the natural and socioeconomic environment cannot be quantified, a rating method of impact assessment is proposed, which allows comparing different types of impacts using the matrix method.

Impact significance is assessed in points. The methodology is based on the four specified parameters of impact: probability, extension, duration, and intensity.

The significance assessment enables the business entity to indicate the need for additional mitigation measures as well as to inform the competent authority, local authority and the public about the most significant

adverse impacts. The results of such assessment will be well understood by all stakeholders as they imply three levels of significance – low, medium and high impact.

The assessment of impacts on the natural environment is carried out according to individual components: climate, atmospheric air, geological environment, soil, water; flora, fauna and biodiversity [19]. The impact assessment on the socioeconomic environment is carried out based on the following components: landscape, human health, socioeconomic situation (employment, communal infrastructure, transport, resources use), historical and cultural heritage.

For the natural environment, zero impact is not taken into account, as any activity will have an effect on the natural environment. Zero impact will only be in the absence of planned activities. The significance rank for each parameter is estimated according to the criteria suggested in Tables 1-4.

Table 1. Criteria for the significance of the impact probability on the natural environment.

Gradation	Impact probability, %	Point
Very low probability	< 10	1
Low probability	10-50	2
Moderate probability	50-90	3
High probability	> 90	4

Table 2. Criteria for the significance of impact spread on the natural environment.

Gradation	Impact spread	Point
Site	Facies, tracts / < 1 km ²	1
Local	Groups of tracts, terrain / 1-10 km ²	2
Landscape	Landscape / 10-100 km ²	3
Regional	Landscape districts, provinces / > 100 km ²	4

Table 3. Criteria for the significance of impact duration on the natural environment.

Gradation	Impact duration	Point
Short-term	Up to 3 months	1
Medium-term	From 3 months to 1 year / Stage of construction	2
Long-term	From 1 to 3 years / Construction	3
Very long-term / (permanent)	More than 3 years / Operation	4

To assess the whole set of consequences of the planned activity on the social and economic conditions, a 5-level ranking with 0 to 4 points is proposed, with a negative and positive sign, both negative and positive factors of impact are ranked.

Each ranking of impact on the components of the socioeconomic environment is determined by the relevant criteria in Tables 5-8.

The impact significance is an integrated (integral) estimate. Impact significance assessment is carried out in several stages.

Stage 1. To determine the impact significance on the individual environmental components, it is necessary to use Tables 1-8 with the criteria of impact and Equation 2.

The impact significance on i -th environmental component is determined as follows:

$$Q_i = Q_i^p \cdot Q_i^s \cdot Q_i^t \cdot Q_i^j \quad (2)$$

Q_i^p – a point of impact probability on i -th environmental component;

Q_i^s – a point of impact spread on i -th environmental component;

Q_i^t – a point of impact duration on i -th environmental component;

Q_i^j – a point of impact intensity on i -th environmental component.

Table 4. Criteria for the significance of impact intensity on the natural environment.

Gradation	Impact intensity	Point
No intensity	Changes in the natural environment do not exceed the existing limits of natural variability / Less than 10% of the object changes	1
Low intensity	Changes in the natural environment go beyond the limits of natural variability, the natural environment is completely self-healing / 10-50% of the object changes	2
Moderate intensity	Changes in the natural environment, which exceed the limits of natural variability, violate the individual components of the natural environment. The natural environment retains the ability to self-healing / 50-90% of the object changes	3
High intensity	Changes in the natural environment result in significant damage to the components of the environment or ecosystems. Separate components of the natural environment lose their ability to self-healing / More than 90% of the object changes	4

Table 5. Criteria for the significance of impact probability on the socioeconomic environment.

Gradation	Impact probability, %	Point
Zero impact	no impact	0
Very low probability	< 10	1
Low probability	10-50	2
Moderate probability	50-90	3
High probability	> 90	4

Table 6. Criteria for the significance of impact spread on the socioeconomic environment.

Gradation	Impact extension	Point
Zero impact	no impact	0
Site	Site of the object	1
Local	Adjacent settlements	2
District	One or more administrative districts	3
Regional	Region	4

Table 7. Criteria for the significance of the impact duration on the socioeconomic environment.

Gradation	Impact duration	Point
Zero impact	no impact	0
Short-term	Up to 3 months	1
Medium-term	From 3 months to 1 year / Stage of construction	2
Long-term	From 1 to 3 years / Construction	3
Very long-term / (permanent)	More than 3 years / Operation	4

Table 8. Criteria for the significance of impact intensity on the socioeconomic environment.

Gradation	Impact intensity	Point
Zero impact	no impact	0
Very low intensity	Positive and negative deviations in the socioeconomic environment correspond to the existing fluctuations of the variability of this indicator before the project implementation / Less than 10% of the object changes	1
Low intensity	Positive and negative deviations in the socioeconomic environment outweigh the existing trends in the changing living conditions in settlements / 10-50% of the object changes	2
Moderate intensity	Positive and negative deviations in the socioeconomic environment exceed the existing conditions of the medium level / 50-90% of the object changes	3
High intensity	Positive and negative deviations in the socioeconomic environment outweigh the existing conditions of the medium-regional or inter-regional level / More than 90% of the object changes	4

Stage 2. The level of significance is determined by the interval of values depending on the grade, obtained in the calculation, as shown in Table 9.

Table 9. Levels of impact significance on the environment.

Point	Impact significance
from +1 to +16	Low positive impact
from +17 to +81	Moderate positive impact
from +82 to +256	High positive impact
0	no impact
from -1 to -16	Low negative impact
from -17 to -81	Moderate negative impact
from -82 to -256	High negative impact

The significances are the same for different environmental components and can be compared with the identified component that is most affected.

The significance levels are determined for all environmental components. If the impact significance, determined for a particular environmental component (atmospheric air, fauna, etc.), is the only one, it is directly used to assess the resulting significance of the impact. However, in practice, one environmental component can be influenced by different sources (activities). Then the integrated (average) assessment of the significance of the impact on i -th environmental component will be the following:

$$Q_{int\ egr} = \frac{\sum_{k=1}^n Q_{ki}}{n} \quad (3)$$

where Q_{ki} – an integrated point of k -th impact (type of activity) on the i -th environmental component;
 n – the number of impacts (activities) on the i -th component of the environment.

It is expedient to analyze the impacts on certain components of both natural and socioeconomic environments from different sources with the help of estimating matrices based on the matrix of Leopold. The

integral (average) estimates for a particular component of the environment are used to determine the significance of the impact.

Conclusions

We use the estimates of tourist potential based on the integrated ranking of individual areas. As a result, it is possible to envisage the appropriate scenarios for the introduction of renewable energy sources, attraction of internal and external investments in tourist activities related to the field of economic complex.

The developed map of quantitative indicators of solar energy potential for the facilities providing renewable energy in the Carpathian region of Ukraine shows the feasibility of introducing the opportunities for using solar energy in the Carpathian region. The results of experiments showed the dependence of energy generation by photovoltaic panels on the meteorological elements of weather conditions, in particular cloudiness, humidity and air temperature. At the same time, it has no direct dependence on the atmospheric pressure and wind speed.

The method for environmental impact significance assessment of renewable energy has been proposed. It is performed after screening and mitigation measures. Due to the fact that the impact of many factors on the natural and socioeconomic environmental components cannot be quantified, a rating method of impact assessment has been proposed, which allows comparing different types of impacts using the matrix method. The methodology is based on the four specified parameters of impact: probability, spread, duration and intensity.

Abstract. The article is devoted to the improvement of control systems for wind turbines by developing fuzzy controllers with higher transient characteristics and low computational costs of identification in comparison with the applied PI controllers. Based on the self-organization method, a fuzzy speed controller of the doubly-fed induction generator (DFIG) of a wind turbine was synthesized, which uses a zero-order Sugeno fuzzy inference system and is made in the form of a block-oriented Wiener model. This regulator is an element of the vector control system of the transistor converter on the rotor side. The results of simulation modeling of the fuzzy controller showed that it provides a lower transition time compared to the PI controller, by 53.59% during acceleration and by 79.76% during braking, and 23.81% less error speed deviations from the reference signal. Such indicators can minimize losses while maintaining the maximum output power point of the power plant. The implementation of the developed system on wind turbines contributes to increasing the efficiency of wind farms, reducing the cost of electricity production, reducing the payback period of equipment, and the sustainable development of alternative energy in general.

Introduction

The sharp increase in the number of wind farms integrated into existing power systems has predetermined the need to increase the volume of electricity generation while reducing the reserves of non-renewable fuel and energy resources, as well as the rapid development of the elemental base of power electronics devices used in wind power converters. As a result, in Europe, the share of wind energy in the structure of electricity production approaches 40%, and in some countries, it exceeds this indicator [1].

The main element of a wind farm is a wind turbine, which converts the kinetic energy of the wind flow into electrical energy [2]. For horizontal axis wind turbines, it was established [2, 3] that the dependence of the output power of the turbine on the angular frequency of generator shaft rotation is unimodal, and its extremum point drifts with changing wind speed. Thus, to ensure maximum efficiency of electricity generation, it is necessary to be able to adjust the rotation speed of the generator shaft. For this purpose, asynchronous generators made according to the scheme of the doubly-fed induction generator (DFIG) [4, 5] are used. The angular frequency of generator rotation, depending on the design, is determined by the difference or the sum of the voltage frequencies supplied to the stator and rotor windings.

At the same time, when finding the extremum point, it is necessary to provide stabilization of the rotation speed.

Given that the wind speed can change quite often and sometimes in a wide range, therefore, high-quality regulation and stabilization of rotation speed, which provides a short transient time, the absence of overshoot and errors in static, will increase the efficiency of electricity production, as a result of reducing losses while ensuring maximum output power of the energy unit. This will contribute to the broader introduction of wind turbines in existing electric networks due to the reduction in the cost of generating electricity and reducing the payback period for the construction of new wind farms. A constant increase in the share of wind energy in the structure of global electricity production will ensure the sustainable development of alternative energy in general.

To regulate the rotation speed of DFIG, the vector control method of the voltage frequency, which is supplied to the rotor winding [4–13].

In such systems, the PI controllers of speed and current are traditionally used [6–13]. Improving the quality of regulation can be achieved using, for example, ARMABIS structures [14] or control systems with a predictive model based on orthogonal functions [15–17], which have high transient rates. More common is the approach that involves the replacement of classical PI controllers with fuzzy logic controllers [18–23].

However, the synthesis of such controllers is a resource-intensive process that requires significant time, material and computational costs and involves the implementation of two stages.

* Corresponding author: epem.mykhailenko@gmail.com

First, by a preliminary expert assessment, fuzzy production rules of the controller's knowledge base are formed, the type of the fuzzy inference system, and the initial parameters of the controller are selected.

After that, structural and parametric identification of the fuzzy controller is carried out experimentally on a real object or a simulation model. Due to high computational loads, they are limited only by parametric identification.

Thus, the development of a method for the synthesis of fuzzy controllers in the vector control system of the wind turbine doubly-fed induction generator with low computational costs is an urgent task.

1 The characteristic of the control object

The structure of the control system for a wind turbine (fig. 1) [6] was adopted as a control object. It consists of an asynchronous generator made according to the scheme of a doubly-fed induction generator (DFIG), the stator of

which is connected to the electric power grid through a transformer, and the rotor receives power from the stator circuit through the converter. The converter consists of two bridge circuits with transistor switches with an intermediate DC-link. The speed control of the motor shaft is directly controlled by the converter located on the rotor side. Therefore its control system will be considered in this work.

The control system includes pulse width modulation unit (PWM), coordinate converters $dq \rightarrow ABC$ and $ABC \rightarrow dq$, which implement the direct and inverse Park-Gorev transform, phase-locked loop (PLL), fixing the position of the spatial vector, reactive power calculation unit in the stator circuit (Q_c calc) and four fuzzy logic controllers – angular speed (ω_m), stator reactive power (Q_s), active and reactive components of the rotor current (I_{dr} , I_{qr}).

The analytical model of the system used in the simulation is considered in detail in [4, 6, 7].

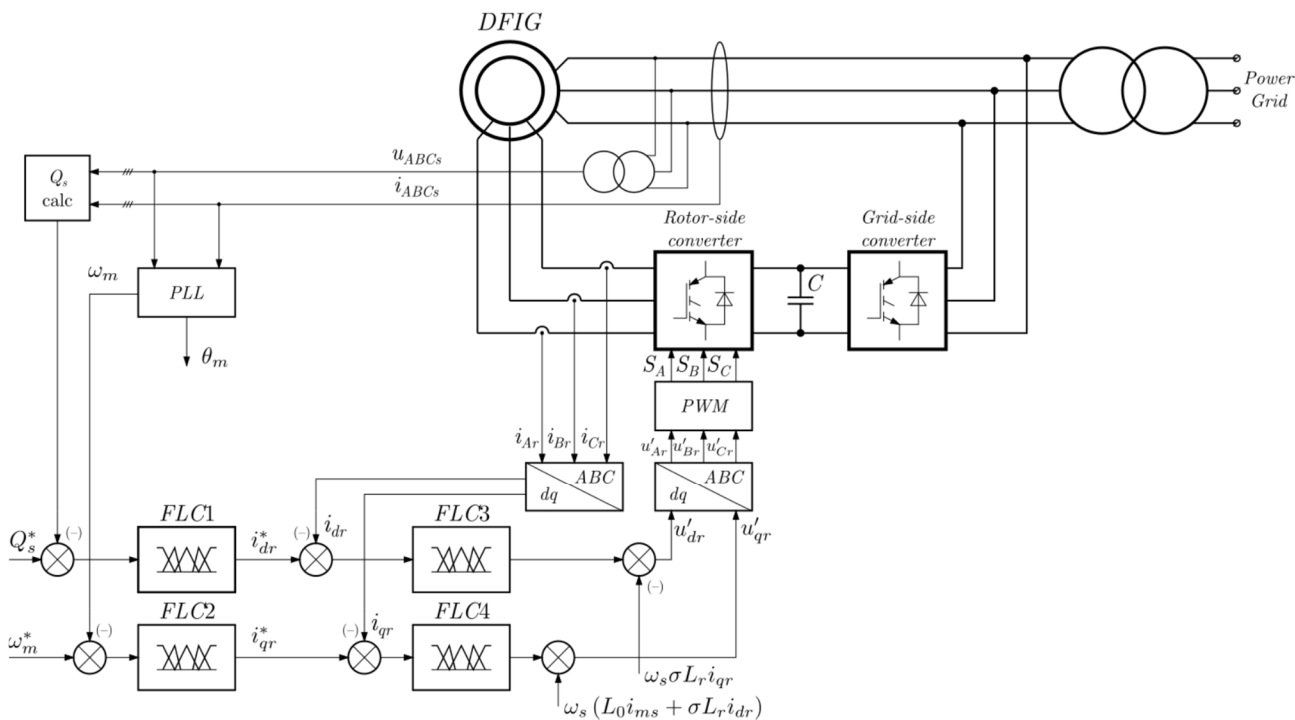

Fig. 1. The block diagram of the vector control system of the rotor-side converter of the wind turbine doubly-fed induction generator.

2 Synthesis of a fuzzy logic controller of the angular frequency of a wind turbine rotation based on a self-organization algorithm

In order to simplify, we represent the speed control system of an asynchronous generator in the form of a closed-loop control system with a fuzzy logic controller (FLC) and a wind turbine fig. 2.

The controller is made in the form of a Wiener structure and consists of a linear time-invariant block (LTI) and a fuzzy inference system unit (FIS) [24].

The controller should provide a minimum deviation of the real angular frequency of the wind turbine generator

rotation ω_m from speed reference ω_m^* , which is formed by an extreme regulation system. In this case, it is necessary to maintain acceptable quality indicators of the transition process.

Fig. 2. The control system structure of a wind turbine with a fuzzy logic speed controller.

It is advisable to evaluate the efficiency of the controller by the mean-square error of a system of the form:

$$MSE = \frac{1}{n} \sum_{i=1}^n (\omega_m - \omega_m^*)^2. \quad (1)$$

To form a set of fuzzy rules of FIS, it is necessary to have a model that approximates the dynamics of a wind turbine, a set of laws for changing input influences ω_m^* , by which the quality of the control system with a fuzzy controller is evaluated, and the structure of the LTI block (in the simplest case, LTI should provide for the input of the FIS control error e and its derivative de/dt [24, 30]).

Discrete fuzzy controller is shown in fig. 3.

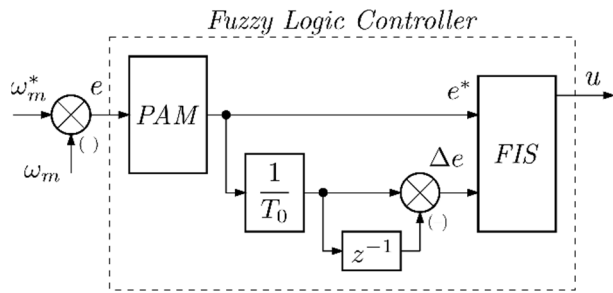

Fig. 3. The block diagram of a shaft speed fuzzy controller of the wind turbine doubly-fed induction generator.

The controller structure includes the PAM block – pulse-amplitude modulator with a zero-order lock, described by the equation: $e^*(t) = e(t_k)$ with $t \in [t_k, t_{k+1}]$, where $t_k = k \cdot T_0$ – is the discrete sampling time, $k = 0, 1, 2, \dots$ – are the discrete-time samples, $T_0 = 0,1$ – is the sampling period.

The fuzzy inference block of the FIS controller implements the zero-order Sugeno fuzzy inference algorithm [24–27, 30].

Let's apply the complementing-optimizing self-organization algorithm of a fuzzy logic inference system [24, 28, 29]. Reduced computational costs characterize this algorithm compared with the known algorithms for building up fuzzy neural networks.

Let's describe the essence of the algorithm concerning the task of constructing a fuzzy speed controller for the rotation of an electric generator of a wind turbine.

The FIS block implements the static nonlinearity of the block-oriented Wiener system of the form:

$$u = \varphi(\vec{\omega}_m), \quad (2)$$

which should minimize the functional $MSE = G(\varphi(\vec{\omega}_m))$, characterizing the quality of the control system according to (1).

Let's suppose that in (2) there is a priori information written as a set N fuzzy production rules of the form: Π_k : **IF** ω_1 is A_{k1} **AND** ω_2 is A_{k2} **AND** ... **AND** ω_n is A_{kn} , **THEN** $u = u_k$, where $k = 1, 2, \dots, N$ – is the knowledge base rule number, ω_j ($j = 1, 2, \dots, n$) – are the vector components $\vec{\omega}_m$, A_{rj} – are the fuzzy numbers with membership functions $\mu_{rj}(\omega_j)$.

A priori information may not be available (i.e. $N = 0$).

Using simulation, the values of functional $MSE = MSE(\varphi(\vec{\omega}_m))$ with the current form of

dependency $\omega_m = \varphi(\vec{\omega}_m)$ are determined.

The algorithm assumes the following sequence of actions.

Step 0 (preliminary). The parameter ε is defined, which determines the accuracy of minimizing the error function of the form (1).

The expert method determines the a priori rule base of the fuzzy logic controller, consisting of N fuzzy production rules. The current number of rules in the database $N_i = N$ is set.

Step 1. If the generated knowledge base is empty go to step 2, otherwise, using the zero-order Sugeno fuzzy inference algorithm and existing production rules, the estimate $\varphi_N(\vec{\omega}_m)$ is determined [24, 30]:

$$\varphi_N(\vec{\omega}_m) = \frac{\sum_{k=1}^N u_k \cdot \xi_k(\vec{\omega}_m)}{\sum_{k=1}^N \xi_k(\vec{\omega}_m)}, \quad (3)$$

where $\xi_k(\vec{\omega}_m) = \mu_{k1}(\omega_1) \times \mu_{k2}(\omega_2) \times \dots \times \mu_{kn}(\omega_n)$ – is the truth degree of the premises of the k -th rule.

According to the estimate (3), the value of the functional MSE_N is determined using simulation (see formula (1)).

Step 2. The knowledge base is replenished with a rule of the form: Π_{N+1} : **IF** ω_1 is $A_{(N+1)1}$ **AND** ω_2 is $A_{(N+1)2}$ **AND** ... ω_n **AND** $A_{(N+1)n}$, **THEN** $u = u_{N+1}$, where $A_{(N+1)j}$ – are the fuzzy numbers with triangular membership functions [24, 30]:

$$\mu_{(N+1)j}(\omega_j) = \begin{cases} 1 - \frac{|\omega_j - \gamma_{(N+1)j}|}{\psi_{(N+1)j}}, & \text{IF } |\omega_j - \gamma_{(N+1)j}| \leq \psi_{(N+1)j}, \\ 0, & \text{IF } |\omega_j - \gamma_{(N+1)j}| > \psi_{(N+1)j}, \end{cases} \quad (4)$$

where $\gamma_{(N+1)j}$ – are the fuzzy number centers $A_{(N+1)j}$.

The formula (3) determines the estimate $\varphi_{N+1}(\vec{\omega}_m, \gamma_{(N+1)1}, \dots, \gamma_{(N+1)n}, u_{N+1}, \psi_{(N+1)1}, \dots, \psi_{(N+1)n})$. Parameter identification $\gamma_{(N+1)1}, \dots, \gamma_{(N+1)n}, u_{N+1}, \psi_{(N+1)1}, \dots, \psi_{(N+1)n}$ by optimizing the function: $MSE_{N+1} = MSE(\varphi_{N+1}(\vec{\omega}_m, \gamma_{(N+1)1}, \dots, \gamma_{(N+1)n}, u_{N+1}, \psi_{(N+1)1}, \dots, \psi_{(N+1)n}))$ by the specified parameters is performed [24, 30].

Step 3. Check inequality:

$$MSE_N - MSE_{N+1} \leq \varepsilon, \quad (5)$$

where $MSE_N = MSE(\varphi_N(\vec{\omega}_m))$,

$MSE_{N+1} = MSE(\varphi_{N+1}(\vec{\omega}_m))$.

The value of N is incremented: $N = N + 1$.

If inequality (5) is not satisfied, go to step 2, otherwise, go to step 4.

Step 4. The knowledge base of the fuzzy logic controller is considered to be formed. The result is a knowledge base consisting of m production rules, while the value of the function is MSE_N .

The FIS knowledge base of the fuzzy speed controller of an electric wind turbine, obtained by an expert method, is presented in Table 1.

The membership functions of the fuzzy variables N , Z , and P have the form shown in fig. 4.

The mean-square error (1) is considered as an indicator of the quality of the control system when a single

step action is applied to the input of the system $\omega_m^* = 1_0(t)$.

Table 1. A set of fuzzy rules of FIS

R1:	IF	e^*	is	P,	THEN	$u = 1$
R2:	IF	e^*	is	N,	THEN	$u = -1$
R3:	IF	Δe	is	P,	THEN	$u = 1$
R4:	IF	Δe	is	T,	THEN	$u = -1$
R5:	IF	e^*	is	Z,	AND Δe is Z, THEN	$u = 0$

Fig. 4. Membership functions of fuzzy variables N, Z and P.

Preliminary modeling of a wind turbine control system, in which a fuzzy logic controller is defined by the five production rules described above, revealed the following result: $MSE = 0,00451$.

Then the synthesis in accordance with the described algorithm was performed. A priori knowledge base corresponds to the Table. 1. The value of the accuracy parameter is $\varepsilon = 0,01$.

The added rules are of the form:

IF e^* is A_{ek} AND IF Δe is $A_{\Delta ek}$, THEN $u = u_k$.

The following parameters of the added rules were optimized: membership function centers γ_{ek} , $\gamma_{\Delta ek}$; consequences of the rules u_k ; total dispersion ψ_k for both membership functions. As a result of the self-organization algorithm, the following results were obtained: total generated rules considering a priori $N = 8$; the value of the mean-square error decreased to $MSE = 0,00286$, which is 1,58 times smaller than the original structure of the controller.

3 Implementation of a fuzzy logic controller of the angular rotation frequency of a wind generator based on a self-organization algorithm

To conduct a computational experiment to assess the quality of the fuzzy speed controller of DFIG, synthesized by the proposed method, a simulation model of the system was developed in the MATLAB/Simulink/Simscape Power Systems software package. The dynamic model of an electric machine is based on the analytical equations presented in [4, 6]. A generator with a power of 2 MW was adopted as an object. The equivalent circuit of the object parameters was taken from [4, P. 181].

During the experiment, the speed reference signal changed according to the following law: when starting the machine $\omega_m^* = 1 p.u.$, which corresponds to the rated rotation speed at the rated wind speed; at 3 seconds, the

reference signal step to $\omega_m^* = 0,9 p.u.$, and at 6 seconds it steps up to $\omega_m^* = 0,95 p.u.$

Fig. 5 shows the speed transients in control systems using PI and fuzzy logic controllers.

Fig. 5. Speed transients when using a PI controller and a fuzzy logic controller.

The analysis of transient processes in speed shows that the application of the developed fuzzy controller provides the best quality of the control system of wind turbine converter in dynamic modes. Thus, the transient time during the acceleration of the asynchronous dual-supply generator for the fuzzy controller was 0.71 s, which is 53.59% less than the PI controller, for which this indicator is 1.53 s. When reduced by 3 s, the speed reference signal reaches 0.9 for the compared fuzzy and PI controllers, and the speed was 0.17 s and 0.84 s, respectively. That is, when the machine brakes, the transition time in the control system with a fuzzy controller is 79.76% less. Let's also note that when applying the PI controller, overshoot is observed. However, this indicator does not exceed 1%, which is acceptable. There is no error in the statics of both controllers. As a result of the deviation of the object output from the reference signal, $MSE_{FLC} = 0,0016$ and $MSE_{PI} = 0,0021$ were made. A 23.81% error reduction indicates the best quality of the proposed zero-order Sugeno fuzzy controller.

Additionally, transient graphs of the main state variables of the DFIG were obtained (fig. 6–15).

Transients in the electromagnetic torque are shown in fig. 6 and fig. 7.

Fig. 6. The torque transient when using the PI speed controller.

Fig. 7. The torque transient when using a fuzzy logic controller.

The peak value of the electromagnetic torque is 103,445 N·m during the acceleration of the motor with a PI speed controller. The use of a fuzzy regulator leads to a decrease in the maximum value of the torque to 97938 N·m, which is 5.32% less. At the same time, when the angular velocity is stabilized in a system with a PI controller, torque fluctuations with an amplitude of 18234 N·m are observed, which is undesirable. In a system with a fuzzy controller, the oscillation amplitude decreases to 1271 N·m, i.e., by 93.02% or 14.35 times.

Transients on the rotor current are shown in fig. 8–11. The use of a PI speed controller leads to oscillations in the d- and q- components of the rotor current (fig. 8). In this case, the amplitude of the q-component oscillations is 2.54 kA. This leads to the fact that, in the steady-state, the oscillations of the rotor current have an undamped character (fig. 9). No oscillations are observed in a system with a fuzzy controller, however, when the machine accelerates, the d-component of the rotor current increases to a peak value of $1.17 \cdot 10^4$ A (fig. 10). This leads to a large current transient (fig. 11). As a result, the transition time in a system with a PI controller is less by 76.62% (0.54 s).

Fig. 8. Rotor current in dq-system using a PI speed controller.

Thus, it is advisable to use the controller of the d-component of the rotor current, which is aimed at increasing speed when using a fuzzy speed controller in the vector control system of the converter of an asynchronous DFIG.

Dynamics indicators for currents in stator windings are close to indicators for rotor currents (fig. 12, fig. 13).

Fig. 9. Rotor currents in ABC-system using a PI controller.

Fig. 10. Rotor currents in dq-system using a fuzzy logic controller.

Fig. 11. Rotor currents in ABC-system using a fuzzy logic controller.

Fig. 12. Stator currents in ABC-system using a PI controller.

Fig. 13. Stator currents in ABC-system using a fuzzy logic controller.

However, as can be seen from fig. 13, in a system with a fuzzy controller, decreases to 2.14 s the transition time during acceleration of the machine (in a system with a PI controller 0.54 s, which is 74.77% less), but there are oscillations with an amplitude of $0.1 \cdot 10^4$ A in steady states.

Figures 14 and 15 show transients in the d- and q-components of the rotor voltage.

Fig. 14. Rotor voltages in dq-system using the PI controller.

Fig. 15. Rotor voltages in dq-system using a fuzzy logic controller.

When using a PI speed controller, there are oscillations with an amplitude of about 200 V for both components. In a system with a fuzzy controller, transients are aperiodic.

A comparative analysis of the dynamics of vector converter control systems on the rotor side of asynchronous DFIG with a traditional PI speed controller

and a developed fuzzy speed controller, which is based on the Sugeno fuzzy inference system of zero-order and Wiener structure, showed that the latter has mainly the best quality indicators transient processes, both in the controlled variable and in the state variables.

Let's note due to which an improvement in the quality of control when using a fuzzy controller synthesized based on self-organization in comparison with traditional PI controllers is achieved. Firstly, the synthesized fuzzy controller implements a nonlinear control law, has a much larger value of the tunable parameters compared to the PI controller and, as a particular case for specific parameter values, it can also implement the linear PI control law, so, in essence, it can be considered as generalization of the law of PI regulation.

Secondly, due to the use of the synthesis algorithm for the base of fuzzy production rules, it is possible to achieve a structure and parameters of a fuzzy controller that is optimal in terms of quality of control and optimized in terms of system control quality.

Thirdly, the choice of the optimal parameters of a fuzzy controller is, in the general case, a multi-extreme optimization problem. The considered self-organization algorithm allows us to consistently increase the controller's knowledge base, thereby synthesizing by sequentially solving optimization problems of low dimension, which partially avoids such difficulties as high computational costs and falling into local minima during optimization.

Conclusions

This article proposes a self-organizing method for the synthesis of fuzzy controllers, based on the zero-order Sugeno fuzzy inference system and having the structure of a block-oriented Wiener system for vector control systems for converters of asynchronous DFIG of wind turbines. When analyzing the indicators of control quality, we considered the implementation of a fuzzy controller of the angular frequency of rotation of the shaft of an electric machine. For a comparative analysis, the classic PI speed controller was used. The results of experimental studies made it possible to establish that the synthesized fuzzy controller provides a shorter transition time in terms of speed, the absence of overshoot, and a smaller standard error in comparison with the PI controller.

The algorithm that synthesizes a fuzzy controller based on the self-organization method is simple and has a low computational load, which allows it to be implemented using digital control devices.

The introduction of vector control systems with fuzzy regulators on wind turbines will allow for high accuracy of regulating the speed of the generator shaft speed while maintaining maximum output power in conditions of changing wind speed. This will increase the efficiency of converting the energy of the wind flow into electrical energy and reduce the cost of generation. The result is a reduction in the payback period of the conversion equipment, and, as a result, an increase in the number of wind farms, which will contribute to the sustainable development of alternative energy.

Subsequent studies will be devoted to the analysis of the dynamic stability of the power grid, which integrates wind turbines using the proposed fuzzy logic controllers.

Abstract. Generating electrical energy from landfill gas (LFG) is a challenge due to its low conversion efficiency. In this study, performance of a NiO/yttria-stabilized zirconia (NiO-YSZ) anode-supported cell operating with LFG feed stream was evaluated. This study investigated the potential of solid oxide fuel cells (SOFC) to produce electricity from LFG generated in pilot scale anaerobic municipal solid waste bioreactors. During the initial experiments, power generation was achieved in the SOFC with direct feeding of the LFG. Different feed flow rates (10 - 25 mL/min) and varying temperature conditions (700 - 800 °C) were also investigated to define the optimal conditions. Experiments were carried out at different feed rates and the successful results obtained from 10 mL/min and 20 mL/min feed speeds. It was also observed that the maximal power values were between 0.10 - 0.11 Watt/cm² for all experiments. This study showed that SOFCs can provide significantly higher energy efficiencies than steam engines for LFG conversion into electrical energy.

1 Introduction

At conventional waste disposal sites, the aim is both to benefit economically from the landfill and re-open the landfill area at the earliest for beneficial use by eliminating the environmental risks. In a closed landfill, the landfill should be monitored by recirculating the leachate back to the waste mass until all the toxic compounds that are harmful to the environment are completely removed. This is possible if the landfill is operated as a landfill bioreactor. Landfill bioreactors increase the moisture content of the waste, thus the waste is decomposed and stabilized faster. The moisture is usually supplied from the leachate produced in the landfill. By recirculating of leachate, water content, nutrients, enzymes and the bacteria are evenly distributed in the landfill. Landfill gas production will increase, and economic benefit will be gained because landfill bioreactors accelerate the decomposition and the stabilization.

Today, the two most important issues related to energy systems are energy efficiency and environmentally friendly energy production with low emission values. These justifications necessitate the use of a high efficiency technology in electricity generation and transmission. Solid Oxide Fuel Cells (SOFC), which generate electrical energy from hydrocarbons with about 70% efficiency, are among the most important technologies to be used in the future with various design and mechanical improvements. The SOFC systems have higher energy efficiency than the other types of fuel cells (up to 85% with the use of heat released during energy production). These systems are environmentally friendly

especially with very low emissions and very quiet operation.

Fuel cells, which are also called electrochemical energy converters, generate electricity and heat through electrochemical reactions by combining gas fuel with an oxidizing gas through an ion-conducting electrolyte. Their efficiency is higher than conventional internal combustion conversions and they produce very little emissions. The difference between the fuel cells of many types depends on the materials used such as electrolyte, anode, cathode and the temperature of use.

The main advantage is the flexibility of the fuel. A variety of biofuels with natural gas, alcohol and hydrocarbons can be used. Fuel cells release electrons, protons, energy and water by using a specific fuel such as hydrogen, methane, methanol, and natural gas. There is no direct combustion in fuel cells. Simply a fuel cell operating principle is based on a simple oxidation-reduction reaction as given in the following equation (Eq. 1).

In this reaction, unlike direct combustion, electrons are switched on in a regular and controlled manner, while oxygen ions are passed through a membrane called permeable ions but not permeable to molecules or metal ions. Generally, fuel cells are composed of membranes, such as electrolytes and electrodes. In these electrodes, oxygen and fuel are ionized to produce electrons and water, and oxygen ions are transmitted through the electrolyte while electrons are transmitted through current collectors. The wider the surface of the electrodes, the more they show catalytic activity. Therefore, it is very

* Corresponding author: cyanan@iau.edu.sa

important that the surface area of the electrodes is high. Because the oxygen ions move in the membrane (the electrolyte), the shorter the distance between the electrodes, the lower the resistance across the electrolyte. The high-porosity electrodes and the fuel cell, which consist of a finely stable electrolyte, help to achieve optimum values for high energy. Various reactions take place on the anode and cathode sides of solid oxide fuel cells. These reactions produce different stresses in these regions. The difference between these voltages makes it possible to use solid oxide fuel cells as a battery. The reactions taking place at the anode and cathode are as follows (Eq. 2 through 7).

The anode portion of the solid oxide fuel cell is supplied with pure hydrogen, hydrocarbons (gasoline, natural gas – CH₄) or alcohols as fuel. These fuels undergo a processing step to obtain molecules used in the fuel cell for reactions in equations (2), (3) and (4), such as H₂, CO and CH₄. Equations (3) and (4) don't really occur because the equations (6) and (7) are realized much faster. If the equation (3) is realized, carbon monoxide (CO) in the hydrogen gas is also used as fuel, but if the equation (6) is realized, this CO provides H₂ from water and is used as fuel. The same applies to methane (CH₄). The cathode side is supplied with oxygen or another gas such as oxygen-containing air.

There are several advantages of solid oxide fuel cells. For instance, fuel processing and desulphurization are improved due to thermal compatibility. Another advantage of fuel cell is that less cell sintering is required when preparing cell materials and time-dependent deformation is reduced, thus increasing the geometric tolerances. Furthermore, less thermal stresses occur at low temperatures, which will reduce the resistance density of the fuel cell. A wide variety of alternatives are provided for the insulating layers used for sealing in the fuel cell.

Today, fuel cells are one of the most important elements for the widespread use of hydrogen energy and other clean and renewable energy sources. Fuel cells are an electrochemical device that directly converts chemical energy into electrical energy and releases heat only as a by-product. Compared to conventional energy converters, fuel cells have superior features such as high efficiency, reliability, modularity, and noise-free operation. Since it generates both electrical energy and heat, SOFC systems can meet all the electricity needs of a house while meeting the heating and cooling needs. While the efficiency in current energy systems is 30-40%, it can reach 90% in low temperature solid oxide fuel cells. Recently, the SOFC

market has been growing significantly [1-8]. Fig. 1 shows a typical solid oxide fuel cell [9].

Fig. 1. A typical methane-fed solid oxide fuel cell [9].

As one of the hydrocarbon fuels, CH₄ is the main component of natural gas, which can be used directly in SOFCs. Previous studies have shown that when CH₄ is used as fuel, several chemical and electrochemical reactions occur on the anode side of the fuel cell [10-12]. The result of these reactions consists of six species, which are deposited carbon (C), H₂, CO, CO₂, H₂O and residual CH₄. A probable reaction in the anode is methane decomposition (Eq. (8)):

Removal of carbon using H₂ gas was studied in detail by several authors. It was reported that the separation of surface carbon from Ni/yttria-stabilized zirconia (Ni-YSZ) causes less damage to the Ni-YSZ structure compared to removal of carbon with oxygen [13]. One study investigated the carbon gasification with H₂ in a Ni-YSZ cell and concluded that the gasification rate varied greatly depending on the H₂ concentration [14]. Pure H₂ gas was observed to completely gasify the carbon on the surface of the cell.

Cell stability is an important criterion for SOFC working with hydrocarbon-based fuels. Tao et al. [15] added an additional functional Ce_{1-x}Ni_xO_{2-y} layer to enhance Ni-SDC (nickel samaria-doped ceria) cell stability using hydrocarbon fuels. This cell exhibited resistance to carbon deposition and showed a partially stable open circuit voltage with 0.8% degradation with dry ethanol.

Landfill gas (LFG) is a product of anaerobic degradation and mainly consists of methane (CH₄) and carbon dioxide (CO₂). Thus, LFG is known as a renewable energy source. Waste-to-energy is a well-known concept for landfill sites; however, the high energy content of LFG is typically converted to electricity by using gas engines. This phenomenon has been proved as a low efficient process and has many problems, such as siloxane contamination inside the engine.

The LFG produced in this study is used in the production of electricity with modular and high technology fuel cell systems which are completely environment friendly and produce water vapor only as an end-product. Within the scope of this study, this will be a unique study on converting landfill gas into electrical energy with fuel cells instead of using steam engines. In this study, LFG from a pilot scale anaerobic landfill bioreactor, which contains 900 kg of municipal solid

waste (MSW), was used as energy source for a solid oxide fuel cell.

2 Methodology

2.1 Theoretical background

The energy conversion efficiency of the fuel cells is not limited to Carnot efficiency and can reach up to 90% with the combined heat and power system. One of the expressions of efficiency for fuel cells is theoretical efficiency. Theoretical efficiency is the expression of the maximum efficiency a fuel cell can achieve and is expressed as follows [16] (Eq. 9):

$$e_{ideal} = \frac{\Delta G}{\Delta H} = 1 - T \frac{\Delta S}{\Delta H} \quad (9)$$

where, ΔG , ΔH and ΔS represent Gibbs free energy, enthalpy and entropy, respectively. Assuming that all Gibbs free energy is converted to electricity for fuel cells, the maximum possible theoretical efficiency can be calculated as follows (Eq. 10):

$$e_{ideal} = \frac{\Delta G}{\Delta H} = \frac{237.34 \text{ kJ.kg}^{-1}}{286.02 \text{ kJ.kg}^{-1}} = 83\% \quad (10)$$

Generally, the lower thermal value of hydrogen is used in theoretical fuel cell efficiency calculations. Thus, the yield is more than 83%. The purpose of this here is not to increase the efficiency numerically, but to compare it with internal combustion engines (Eq. 11).

$$e_{ideal} = \frac{\Delta G}{\Delta H_{lowerheat}} = \frac{228.74 \text{ kJ.kg}^{-1}}{241.98 \text{ kJ.kg}^{-1}} = 94.5\% \quad (11)$$

In fuel cells, cell potential decreases during operation due to polarizations. Therefore, the net yield depends on the cell potential V_{cell} . The voltage efficiency can be defined as follows (Eq. 12):

$$e_{voltage} = \frac{V_{cell}}{V_{max}} \quad (12)$$

where, V_{max} is the Nernst potential, or the maximum voltage potential, and V_{cell} is the actual cell potential.

Another efficiency expression in fuel cells is called fuel usage efficiency. Fuel utilization is an expression of how much fuel and oxidant is supplied to the system during conversion. Under actual operating conditions, not all fuel sent to the fuel cell can be converted into energy. In this case, the fuel and some of the oxidant supplied to the system leave the fuel cell before it converts into energy. Accordingly, fuel use is expressed as the ratio of the fuel flow corresponding to the electrical current generated in the system to the actual fuel flow sent to generate the same current.

Three different efficiencies are expressed for fuel cells. These efficiency statements affect the overall operating status of the fuel cell. Therefore, the actual efficiency of the fuel cell is equal to the three efficiency expressions, the theoretical efficiency, the voltage efficiency, and the multiplication of the fuel usage efficiency (Eq. 13).

$$e_{real} = e_{ideal} \cdot e_{voltage} \cdot e_{usage} \quad (13)$$

The stoichiometric ratio, which is the inverse of faradic efficiency, is defined for fuel cells. Stoichiometric ratio is a type of expression that is often used to prevent excess oxidant from being sent during the electrochemical reaction (Eq. 14 and Eq. 15):

$$\lambda_c = \frac{1}{\varepsilon_c} \quad (14)$$

$$\lambda_a = \frac{1}{\varepsilon_a} \quad (15)$$

Anode and cathode stoichiometry for fuel cells is usually more than 1. In other words, more fuel and oxidant are provided above 100% fuel usage value. In the literature, stoichiometric ratio of hydrogen is between 1.2 and 2, while air stoichiometry ranges between 1.5 and 4. In addition, there are many misleading data in the literature regarding fuel efficiency. Fuel usage efficiencies vary according to the flow rate and fuel cell operating voltage [16].

2.2 Design of LFG-SOFC system

LFG was collected from the pilot scale landfill bioreactor (LBR) to a flexible gas sampling bag. Then it was slightly pressurized to sustain a constant flow during the SOFC energy conversion experiment. Inlet flow of LFG was controlled with a gas flowmeter, and different flow rates were investigated to identify the maximal current produced in the SOFC system. Solid oxide fuel cells were first reduced with hydrogen gas to allow nickel oxide-nickel conversion. Then, when the operating temperature reached 775 °C, the input LFG was fed into the fuel cell at different speeds (10 – 20 mL/min). The gas balloon was gently pressurized and fed at constant speed with the help of rotameter. During SOFC experiments, voltage, power and current values were recorded instantaneously on computer assisted system in order to monitor the efficiency of energy obtained from LFG.

Anode supported micro tubular solid oxide fuel cells were used in this study. The cells were developed in a nanotechnology laboratory. Anode electrolyte and cathode materials were NiO-YSZ (50/50, weight/weight) composite powder, 8YSZ (%8 Y₂O₃ doped with ZrO₂) and LSM (lanthanum strontium manganite), respectively. Anode support layers were prepared via thermoplastic extrusion. The active surface of cathode was 3 cm².

The composition of LFG produced from pilot scale anaerobic bioreactors was measured by Agilent 6890N gas retention detector gas chromatography (GC-TCD). In GC-TCD analysis, Agilent HP-PLOT/Q model capillary column was used for CO₂ capture and Agilent HP-MOLSIEVE capillary column was used for separation of other gases. Detailed content of LFG used in this study is presented in Table 1. To determine the energy conversion efficiency of the SOFC experiment, voltage, power and current were recorded during the experiment by computer-based control system (Fig. 2).

Table 1. LFG content used in SOFC experiments

Gas	Unit	Value
CH ₄	%	51,04
CO ₂	%	27,48
N ₂	%	12,68
O ₂	%	3,53
Others	%	5,27
H ₂ S	ppm	1105

Fig. 2. Experimental set up with fuel cell.

3 Results

LFG is a mixture of gas with high energy value, which mainly contains CO₂ and CH₄ produced by anaerobic biodegradation of organics in landfills. LFG is converted into electrical energy with very low efficiency (30-40%) by conventional internal combustion gas engines. Producing electrical energy from chemical energy with an efficiency of approximately 60% from hydrocarbons, SOFCs will be among the most important energy conversion technologies to be used in the future.

The current-voltage (i-V) and the corresponding power density current density figures when the SOFC is fueled with pure CH₄ and landfill gas are shown in Fig. 3 and Fig. 4, respectively. The open circuit voltage (OCV) values for the Ni-YSZ cells at 775 °C were measured as 0.42-0.90 V with pure methane as the fuel and 0.21-1.00 V with landfill gas as the fuel with feeding speed of 20 mL/min and 0.14-0.98 V with feeding speed of 10 mL/min (Fig. 3 and Fig. 4). The open circuit voltage values for the Ni-YSZ cells at 750 °C were measured as 0.09-0.97 V with landfill gas as the fuel with feeding speed of 15 mL/min and 0.08-0.98 V with feeding speed of 20 mL/min (Fig. 5).

Fig. 3. Electricity production from pure methane gas with fuel cell with feeding speed of 20 mL/min at 650 °C.

Fig. 4. Electricity generation from LFG with fuel cell with feeding speed of 10 mL/min and 20 mL/min at 775 °C.

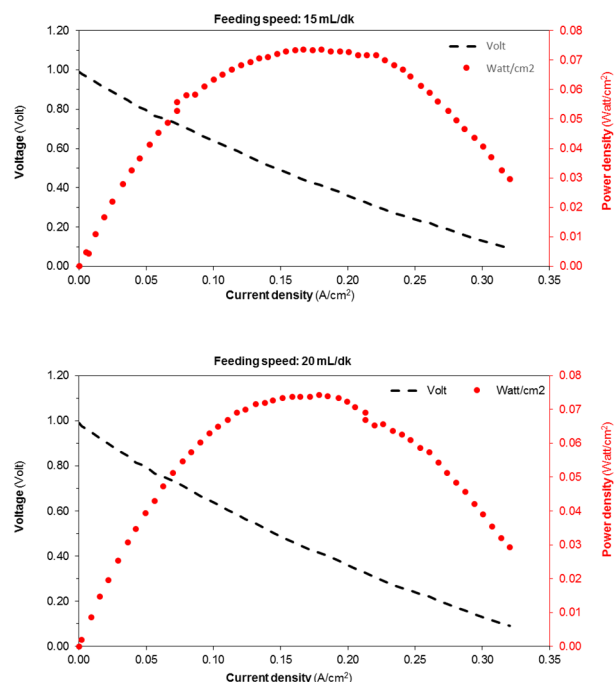

Fig. 5. Electricity generation from LFG with fuel cell with 15 mL/min and 20 mL/min at 750 °C.

Experiments were carried out at different feed rates and the successful results obtained from 10 mL/min and 20 mL/min feed speeds and the results of the pre-test performed with pure methane gas at 650 °C were compared in Table 2. It was also observed that the maximal power values were between 0.10 - 0.11 Watt/cm² for all experiments. It can be seen from Fig 3, Fig 4, and Fig 5 that the highest power densities for the Ni-YSZ cells were achieved at the highest temperature of 775 °C tested.

Table 2. Electrical voltage, current and power values obtained from SOFC experiments at 775 °C.

Feeding gas	Feeding speed	Voltage	Current density	Power density	Maximum power
	mL/m	Volt	A/cm ²	W/cm ²	W/cm ²
%100 CH ₄	20	0,700	0,125	0,088	0,114
LFG (%51 CH ₄)	20	0,705	0,121	0,085	0,110
LFG (%51 CH ₄)	10	0,709	0,104	0,074	0,099

4 Discussion

Fuel cells are an efficient, combustion-free, virtually pollution-free power source for a green energy production that is perfectly environment-friendly, completely silent and has a few moving parts. The desire for solid oxide fuel cells to be manufactured at larger sizes, with more power, less emissions and lower costs has led to new developments. It was estimated that the fuel cell production has grown by 44% since 2014 – parallel to the increase in solar and wind energy in previous years. This rapid growth is driven by increased demand for energy diversification and the employment of alternative energy sources. Because of increased carbon emissions and extreme climatic events, businesses and communities demand three things: more affordable electricity, more durable power and cleaner energy.

The production of electricity as a result of an electrochemical reaction rather than fuel combustion shows that fuel cells are much cleaner and more sustainable than conventional combustion-dependent technology. Fuel cells are more environmentally friendly in two ways: first, they avoid spreading harmful impurities such as NO_x and SO₂, which are associated with respiratory diseases and poor air quality throughout the world, and the second they reduce greenhouse gas (GHG) emissions. Fuel cells are continually proving to be the most efficient, resilient, and sustainable form of alternative energy generation. As an energy solution that provides both sustainability and power security, fuel cells are the leading power generation technology for businesses and communities now and in the future.

A solid oxide fuel cell fueled with landfill gas has the potential to generate electrical energy, which seems to be an alternative to incineration and landfill applications. However, separating renewable hydrogen from biomass and landfill gas is not an easy task. Furthermore, construction and operation costs are quite high, which can cause customers to avoid risk. Today, those who started using solid oxide fuel cells early started to use government tax incentives and sustainability program grants.

Some of the systems that use direct fuel cells generally operate at 538 °C and use biogas produced by anaerobic digesters. In most projects, the purified landfill gas can be injected into an existing natural gas pipeline that directs it

to direct fuel cell units elsewhere. However, it is a fact that landfill gas contains moisture, sulfur and CO₂. For landfill gas-fueled fuel cell systems, desulphurization and moisture removal is required, while stricter pipeline quality is required for bio H₂, thus CO₂ must be removed for directed biogas systems.

5 Conclusions

Nickel-based anodes are suitable for SOFC technology when hydrogen gas is used as fuel. Biogas-SOFC energy system, which uses landfill gas as a feed source, can meet both electrical and thermal energy needs for homes away from the grid. However, the obligation to clean up biogas can have a major impact on the total investment and operating costs and thus complicate the procurement of technology among non-rural communities. Therefore, the choice of a cleaning system technology, in particular for the small-scale biogas-SOFC energy system, should also meet the impurity levels required by SOFC, typically less than 2 ppm for H₂S. For small-scale biogas-SOFC systems, a suitable gas cleaning unit must be very efficient to maintain low pollution levels and also economical for small-scale systems.

In this study direct landfill gas SOFC operation using landfill gas was successfully conducted on anode electrolyte and cathode materials of NiO-YSZ composite powder and LSM at 775 °C. This study showed that direct electro-oxidation of landfill gas in SOFCs has a great potential. SOFCs can provide intrinsically higher efficiencies than steam engines. It is very clear that SOFCs can offer many advantages for landfill gas conversion to electrical energy.

PhotosynQ – cloud platform powered by IoT devices

Andriy Herts, Ivan Tsidylo, Nataliia Herts, Ljubov Barna, and Stanislav-Ivan Mazur*

Ternopil Volodymyr Hnatiuk National Pedagogical University, 2 Maxyma Kryvonosa Str., Ternopil, 46027, Ukraine

Abstract. This article describes how to connect to PhotosynQ and some of the features of a cloud service. The focus is on organizing communication between the web service and the Internet of Things. An example and procedure for integrating a number of digital encoders that are not included in the list supported by the default platform through modification of the open-source base firmware is given. It has been suggested that in the future, a number of tools can be designed in the future, including for environmental monitoring, using basic digital sensors included in the so-called Arduino UNO Kit kits and more. It is emphasized that the PhotosynQ web platform, which is related to the SaaS cloud computing model, is an environment for collecting, analyzing, deriving and discussing results where research protocols and calculation procedures are open access. Its primary focus is only on working with a specific list of dashboards, offset by the openness of the software itself, which provides communication with the platform.

1 Introduction

Now there is a growing need for cloud services, computing. Cloud technology is becoming an integral part of many companies and according to IDC forecasts [1], up to 67% of IT infrastructure and software will be implemented with its use.

Over the last 5 years, they have changed not only the IT industry. Ninety percent of US educational institutions have switched to cloud technology [2]. Scientific institutions of the world are no exception.

A variety of web-based software tools used in large-scale science applications help with computation, data integration, analysis, and process automation. Using information obtained through computational procedures, they help scientists to solve applied problems and facilitate the dissemination of data. Here, at least, one should mention the complex research in the field of bioinformatics, the study of brain biology, using network and / or web-based tools for the work process [3].

Cloud technologies and services based on them, in particular PaaS, SaaS, IaaS [4], are gradually becoming platforms through which one can explore the environment. Based on these solutions, researchers can build the tools they need to build databases, making all the settings remotely via the Internet.

Of course, today we do not have to talk about a universal cloud service that would satisfy the needs of the scientific community as a whole, and the need to simultaneously use all three of the key aforementioned services that cloud services provide. The diversity of the data set, their heterogeneity, the differences in the amount of data sets, and therefore the need for different computing capacities, the lack of a unified interface for communication and data exchange all require individual cloud service architecture for the specific tasks of users

and researchers. However, the main advantages of using cloud platforms are as follows: speed of creation of new applications, flexibility and scalability of the system.

With the development of RFID (Radio Frequency Identification), WSN (Wireless Sensor Network), NFC (Near Field Communication) and M2M (Machine-to-Machine), which, when integrated with the Internet, allow for easy communication of various technical devices (“things”), another type of platform, namely IoT cloud platforms, is gaining in popularity.

IoT allows you to create a combination of smart devices interconnected by communication networks, and people. Together, they can create a variety of systems, for example, to work in environments that are inaccessible to humans, etc.

With the development of IoT, more objects (“things”) will connect to the global network. In this way, new opportunities will emerge in various spheres of human activity, and new perspectives will be opened to improve the quality of life of the population, in particular by improving the food security of mankind. There is every prospect that in the future, “things” will become active participants in business, information and social processes, where they will be able to interact and communicate with each other, sharing information about the environment, reacting and influencing the processes occurring in the surrounding world.

As platforms grow, so does the need to explore their capabilities and the tools they provide. One of the cloud platforms that is designed to produce exceptionally high-quality field-based scientific results is PhotosynQ [5].

PhotosynQ is first and foremost a network of open Internet data on the status of plant organisms and their phenotyping [5]. Basically, the primary data is obtained through the operation of a tool, a device [6] that captures information from plant objects. The latter is based on the

* Corresponding author: tsidylo@tnpu.edu.ua

chlorophyll fluorescence parameters and characterizes the course of the primary photosynthesis processes. The final data are obtained by processing the primary data and visualizing them with on-line platforms.

This creates a communication platform that connects a large number of researchers, groups of researchers, breeders, farmers, teachers and civilian scientists, creating new opportunities in the direction of research management, raising the level of knowledge about the phenomena and objects under study. Existing PhotosynQ projects are designed to remove barriers between laboratory and field research through the development of tools to study, including the state of plants in dynamic natural environments, etc. [7].

The platform itself is easy to use. According to the developers, it allows not only different users to exchange, compare and analyze the results of the research, but also in its specific setting, to take into account the specifics of the research, to easily adapt the researcher to their own needs.

The stated principles of operation of the said platforms [8] comply with the basic principles of the Internet of Things [9], the key of which is the ability of each object to send and receive data via a personal network or the Internet. This makes the PhotosynQ platform cloud-oriented and capable of communicating with things.

2 Analysis of recent research and publications

Plant phenotyping [8] is first and foremost the main goal of the cloud-oriented PhotosynQ platform. Over the past few years, researchers from more than 25 countries have been using it actively, making hundreds of thousands of measurements. A number of different projects on plant breeding, agronomy and physiology have been obtained and uploaded [8]. Frequent sources [10] inform about the use of PhotosynQ for educational purposes. For instance, Delaware Valley University (USA) student research course, which is part of the University's Experience360 program and is aimed at providing students with practical research experience in the field of biology, is based on the application of this online platform [11]. In total, as of October 2018, the total number of measurements received and processed by PhotosynQ reached one million.

However, one should pay attention to its capabilities in the direction of exchange, data analysis, the ability to customize to meet the needs of both researchers and users in general. In the long run, this can bring it out of the scope of the use only by plant object researchers and provide a tool for collaborative research, such as the natural environment as a whole.

Figure 1 shows the architecture of the PhotosynQ cloud platform [8], which was developed at Michigan State University (Michigan State University, MSU, USA) [5]. The primary and leading role in this scheme is played by devices that can collect all kinds of information, data and disseminate them over communication networks. Therefore, the “thing” in our

case is represented by the “device” MultispeQ [8]. This is not in contradiction with Recommendation ITU-TY.2060 [12], concerning the definition of the Internet of Things, since the said device is capable of communication.

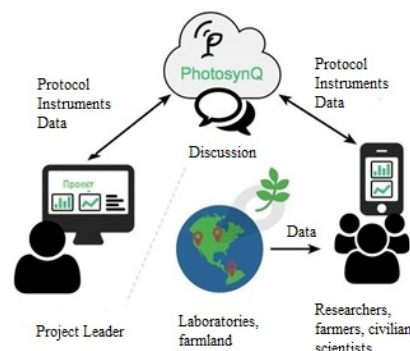

Fig. 1. The principle of organization of the PhotosynQ network [8]

With regard to communication itself, it is known that many network technologies are provided for IoT such as global networks, local area networks, self-organizing wireless networks (ad-hoc) and mesh networks [13]. These communication networks transfer the data collected by the devices to the respective software applications, and transmit commands from the software applications to the devices. Above, we [14] characterized ThingSpeak cloud service as a means of training biology students to monitor and estimate the air pollution of the surface layer of the atmosphere. The prototype that provides monitoring of the human respiratory zone in two districts of the city of Ternopil on the content of suspended particulate matter PM10 and PM2.5 was developed. The main components of the instrument were implemented via microcontroller development system – Teensy 3.2, sensor module (temperature, humidity, pressure) BME280, SenseAir S8 carbon dioxide sensor module, PMS3003 air pollution sensor, Wi-Fi module ESP-01 and online ThingSpeak platform for storing and processing data.

In the case of PhotosynQ, communication between the device and the online platform is accomplished through the mobile PhotosynQ App or its Desktop version [8] using Bluetooth technology, in particular. The power of a mobile device with the appropriate application installed is not only involved in the management and collection of data, but is also used for initial calculations. In the end, the application sends the data to the cloud.

Analyzing the literature, documentation and information support of the site [8], we note that the developers were guided by Open Hardware principles when designing a tool integrated with the PhotosynQ cloud platform [15]. Open access contains documentation on its use and describes the main specifications [7]. The procedure for creating protocols for the study organization is described in detail, the procedure for creating protocols (instructions) for device control is described as well [8]. The latter involve access to a single sensor, both the structural component of the

device and all sensors in general. Given the number of encoders (sensors) that is supported by the firmware of the device, which was created by current owner and project participant Our Sci Greg Austic [16] and Jon Zeeff, we are able to analyze a fairly wide range of physical parameters of the environment or objects, whenever necessary.

According to the developers [8, 17], the device is designed so that if necessary, it can integrate additional necessary extensions, sensors, etc. The core of the “thing” is the Teensy microcontroller [18] that controls all components, sensors. Given that open-source firmware [9] is a principle (specify the type of license), it creates the ability to modify the tool, “thing” for one’s own needs.

Therefore, a sufficient condition for communication with the PhotosynQ on-line platform is a Teensy microcontroller with appropriate firmware [17]. Its analysis seems to suggest that, subject to certain, sometimes not very significant changes, support for a much wider range of intelligent sensors (transmitters) can be obtained. Thus, to get a simple tool that will significantly expand the research or teaching tool of a researcher or a teacher accordingly.

3 The results of the research

The hardware to communicate with the PhotosynQ platform.

Our measurement system consists of intelligent, digital sensors (DS), measuring converters (see Fig. 2), which are connected to the signal processing system. The latter is represented by the Teensy 3.2 hardware and computing platform [18]. The hardware, according to its technical characteristics, is able to collect temperature data (−40 to +85 °C, ±0.5 °C), relative humidity (0–100%, ± 3%), atmospheric pressure (300–1100 hPa, ±1.0hPa), carbon dioxide (CO₂) level (0.04% to 2%), PM concentration (PM 2.5, PM 10, µg/m³), (measurements range from 0.3 to 1.0; from 1.0 to 2.5; from 2.5 to 10 microns) in the air, the level (ppm) of carbon monoxide (CO) (1–1000 ppm), nitrogen dioxide (NO₂) (0.05–10 ppm), ethanol (C₂H₅OH) (10–500 ppm), hydrogen (H₂) (1–1000 ppm), ammonia (NH₃) (1–500 ppm) methane (CH₄) (> 1000 pmm), propane C₃H₈ (> 1000 ppm) and iso-butane (C₄H₁₀) (> 1000 ppm).

Considering that among our proposed DSs, the components are those supported by the default platform (Fig. 2), i.e. their libraries, the code is integrated into the MultispeQ base firmware [17], accessed according to the instructions [19], in particular through the protocols of the PhotosynQ App mobile application [8].

To expand the list of supported DSs, we have made changes to the MultispeQ firmware. In particular, for the Grove Sensor – Multichannel Gas Sensor MiCS-6814 [22], the Seeed Technology Inc. library is built into the definer.h file [17], for Plantower PMS 3003 sensor – PMS Library-1.1.0 [23]. The code (C++) of both these CAs, which contains its own variables and a list of commands, has been integrated into the firmware as separate functions (Fig. 3), which can be called from

anywhere in the sketch, in particular, using the general format of the line instruction (construction) [24]:

```
...
//process single commands
switch (val) {
case hash("get_pms"):
    Serial3.begin(9600);
{
    PMS pms(Serial3);
    PMS::DATA data;
    pms.read(data);
    Serial.println(data.PM_AE_UG_1_0);
    Serial.println(data.PM_AE_UG_2_5);
    Serial.println(data.PM_AE_UG_10_0);
    delay(100);
}

    Serial3.end();
    break; }
```

Fig. 2. The main components of the prototype for the assessment of the basic physicochemical parameters of the natural environment (A – BME280 [19], C – SenseAir S8 [20], E – HC-06 [21] are supported by the default PhotosynQ platform; B Grove – Multichannel Gas Sensor [22], D PMS 3003 [23] – require additional firmware.

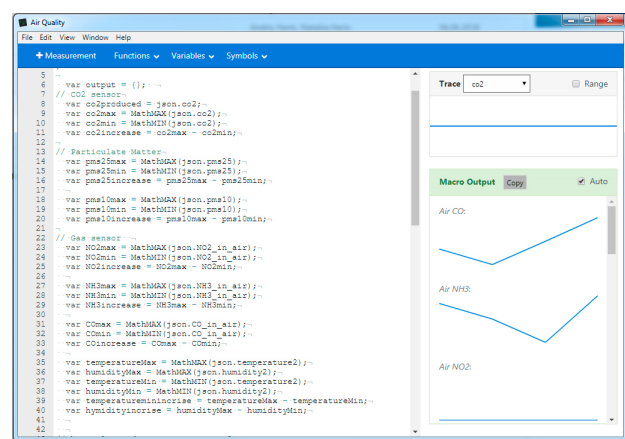

Fig. 3. The PhotosynQ Desktop application window for working with macros [8].

To provide communication with the firmware, we used an open access protocol containing instructions written in JSON [25]. It determines which of the DSs will be involved at a particular moment of time. In fact, access to our integrated sensors is provided through a command in the protocol:

```
[ "pms", 0 ], [ "mgs", 0 ]
```

where, “pms”, “mgs” refer to the corresponding variables contained in the firmware.

Therefore, in order to measure all the above-mentioned physicochemical parameters of the medium and to use the DSs mentioned in the work (see Fig. 2), the following construction should be used in the protocol:

```
"environmental_array": [  
  [ "co2", 0 ],  
  [ "temperature_humidity_pressure2", 0 ],  
  [ "pms", 0 ],  
  [ "mgs", 0 ]  
]
```

The protocols are related to macros [8]. The latter are written in JavaScript and run after the protocol is complete. By providing computations where the primary data is from the JSON CD values, the macros are responsible for outputting the final calculations on the PhotosynQ Desktop personal computer application or, in the case of a mobile phone, or a tablet, in the PhotosynQ App. Actually a macro for calculating the maximum and minimum concentration of CO₂, the content of particulate matter (particulate matter, (PM)) in the atmosphere, in PhotosynQ Desktop application (Fig. 3) [8] has the following form:

```
var output = {};  
// CO2 sensor  
var co2produced = json.co2;  
var co2max = MathMAX(json.co2);  
var co2min = MathMIN(json.co2);  
var co2increase = co2max - co2min;  
  
// Particulate Matter  
var pms25max = MathMAX(json.pms25);  
var pms25min = MathMIN(json.pms25);  
var pms25increase = pms25max - pms25min;  
  
//Show value and name in output CO2  
output["co2.array"] = json.co2;  
output["CO2 increase"] = co2increase;  
output["Max CO2"] = co2max;  
output["MinCO2"] = co2min;  
  
//Show value and name in output  
// Particulate Matter output  
output ["PM2.5"] = json.pms25;  
output["PM2.5 increase"] = pms25increase;  
output["Max PM2.5"] = pms25max;  
output["Min PM2.5"] = pms25min;
```

When using only PhotosynQ Desktop software for writing macros and protocols, the platform's web interface (Fig. 4) is a place where authorized users can create their own projects [8], view, analyze data, search for projects of other users and, if necessary, join them. Actually, the project acts as a kind of data organization [8].

The project we created with the name “Air Quality” is based on the protocol of the same name (protocol ID 1492), which was described above and contains, in addition to the description, a series of questions that must be answered by each project participant before directly performing the measurement.

This approach provides the necessary structuring, categorization of the obtained data and facilitates their further processing, including statistical data.

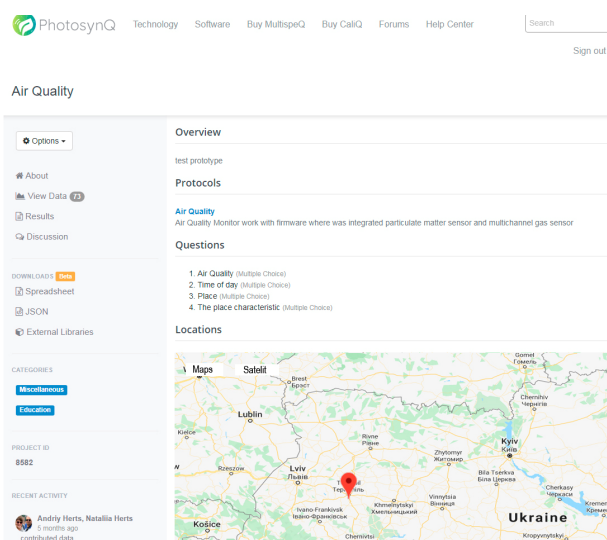

Fig. 4. Web-based Air Quality project interface on the PhotosynQ platform [8].

In order to participate directly in the project (subject to the creation of the above-mentioned prototype), Air Quality, and make measurements, it is necessary to: 1) ensure communication of the prototype with PhotosynQ App or PhotosynQ Desktop; 2) choose from the list of projects needed; 3) answer all the questions listed in the project; 4) take measurements. After the measurement is completed, it is possible to view its results directly on the screen of a mobile phone, tablet (Fig. 5) or the monitor of a personal computer when using the desktop version of the application. After evaluating the quality of the data, it is confirmed or canceled to send the results directly to the website.

The platform has a whole set of tools for statistical analysis (t-test, chi-square test, ANOVA) and data output. If necessary, for additional statistical processing of the obtained data, in our opinion, it is advisable to use the possibilities of R software environment for statistical calculations, analysis and data representation in graphical form. Providing that there are several ways to access the source data and there is a possibility of downloading them in .csv, .xlsx, json formats, the choice of priority method becomes subjective.

In our opinion, the ability to import datasets directly from a project in Python or R is a very promising solution. In particular, PhotosynQ R (PhotosynQ R package) [7] allows to access our project data by its ID number and generate the required data frame from the R environment.

To generate a data frame file containing the Air Quality project data in RStudio, an integrated development environment (IDE) for R, we executed the recommended [7, 8] set of commands:

```
PhotosynQ::login("login@domain.com")  
ID <- 8582  
df <- PhotosynQ::getProject(ID)
```

The procedure described in [9] for accessing RStudio software to our aforementioned project with ID number 8582 was successful. For RStudio Cloud, it was similar and did not require the installation of additional libraries.

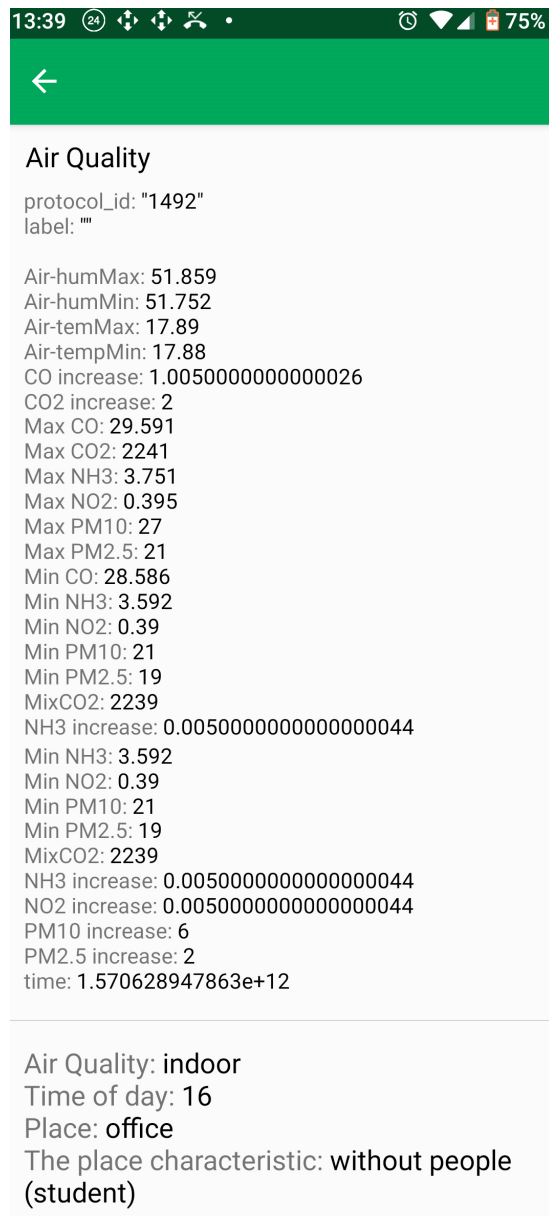

Fig. 5. Presentation of measurement results of the Air Quality project in PhotosynQ App.

Having access, after installation in the Jupyter Notebook environment, which among Data Science professionals is de facto standard for rapid prototyping and analysis of data, PhotosynQ-Python.git from GitHub, to the Web site API [7], each authorized member receives access not only to project data, but also they receive the ability to extend the boundaries of cooperation and beyond.

4 Conclusions and prospects for further research

Currently, hardware connectivity and “communication” with most cloud services is happening through an open API. Ready templates for data connection and processing are offered for this purpose. The PhotosynQ platform provides a data access API, but there is no real-time data visualization and a number of other APIs offered by the

services, including ThingSpeak, Ubidot [26, 27]. At the same time, there is an opportunity to display general information about the projects, results and location of the research, etc. This seems logical given that the platform we are researching is primarily aimed at researchers, educators, farmers and citizens who collect, analyze, discuss and exchange information received through portable devices. Considering that the main landmark of PhotosynQ is the collection of data in a well-defined procedure, the user determines the time, place and duration of the process.

The existing firmware contains code that describes the procedure for connecting to it Desktop or mobile application. After receiving information from the device, the commands (procedures) are sent back in JSON format, as they already contain parameters that will determine and define the work of the DSs, the sequence, duration of their work, etc. Therefore, unlike the services mentioned above, which interrogate connected CDs sequentially with a certain user-defined and periodic frequency, the MulispeQ firmware [17], designed to interact with PhotosynQ, is organized so that the user determines the data acquisition procedure, the number of DSs involved at a given time, the sequence and duration of their work, etc. The web platform itself is a place for data collection, analysis and exchange and is not inherently an IaaS or PaaS platform. At the same time, the platform has a whole arsenal of tools for statistical analysis (t-test, chi-square test, ANOVA) and data output.

Therefore, the available firmware used by the PhotosynQ platform to communicate with the fluorometer allows, without further modification, together with the Teensy 3.2 and DSs to obtain, if necessary, a portable measuring device. Support by the BME280, K30 DSs firmware [9] to the color sensor TCS34715 [9] will allow you to evaluate not only temperature, relative humidity, atmospheric pressure, CO2 content, but also the level of illumination in the suites and the spectral distribution in the RGB range. Support for MDX MLX90615 [9] will provide a reading of the surface temperature of the study objects. Available code for the MAG3110FCR1 encoder [9] will allow you to work with a magnetometer and the like.

The suggested approach of inserting additional code into the firmware and successfully plugging in additional sensors, in particular Grove - Multichannel Gas Sensor MiCS-6814, “PMS 3003” enables researchers to tailor the firmware to their own needs, experimenter’s needs, or training process, in particular. By inserting the encoder code into the popular kits Arduino UNO Kit or their counterparts from DFRobot, Elecrow, etc., we will get a tool that organizes the communication of a dozen marketed sensors with IoT-oriented PhotosynQ cloud platform, and the similar ones which will greatly enhance the capacity of not only researchers, teachers but also students.

We thank Greg Austic (Our Sci LCC member/owner) for technical assistance and new opportunity, Sebastian Kuhlger (PhotosynQ LLC) and PhotosynQ team for their cooperation.

Geoinformation system for managing non-regular passenger transportation

*Andrii Yefimenko, Alex Kuzmenko, Halina Marchuck, Roman Petriv, and Inna Suhoniak**

Zhytomyr Polytechnic State University, Department of Computer Science, 103 Chudnovska Str., Zhytomyr, 10003, Ukraine

Abstract. Today there are a large number of different companies involved in non-regular passenger transport. Most of them use special software to reduce the speed of order processing and for better service management. Such programming tools often provide a convenient system for processing orders and a user interface for the contractors. Therefore, such companies have already forced out other competitors from the market of passenger transport. The purpose of the research is to develop and implement an algorithm of driver's path optimization and to develop a decentralized on-line service, oriented on support of the management of non-regular passenger transport, consisting of a service for car ordering, a service for processing and executing orders and a service for managing internal private organizations. Each service is an application accessible from both a web browser and a mobile device. In the paper the theoretical basis of the management of passenger transport has been analyzed and the basic problems have been defined. The route optimization task, which was reduced to the asymmetrical task of the salesman, was initiated. The Little algorithm for the resolution of this task was used.

1 Introduction

Modern management services of passenger transportation provide a convenient interface and ease of using. But they don't solve all user problems.

There are many different schemes for managing passenger transportation. Some companies have their own vehicle fleet, hired drivers and a database of customers. The other companies provide a centralized service with a database of drivers, customers and orders, and the client applications, used by drivers and passengers for their interactions.

There are a lot of advantages in such services. The driver himself decides the time and the place of his work. He may choose a favorable order for him. Passengers may also choose drivers and share impressions about the trips with them. But also, there are some problems. Trust and security are some of them. Even a rating system and reviews will not always help to solve these problems.

The problem of trust is suggested to resolve with the help of private groups, the drivers and the passengers will be joined in. These groups will be closed and participants will have an access to activate the private mode, thus any other driver or a passenger could not see their order in the system. So, the passenger transportation will only be done by trusted drivers. Drivers and passengers will also be able to combine a private and public mode to achieve the best efficiency of the work.

That is why the development of a service that solves these problems and provides a convenient user interface for passengers, drivers and, most importantly, private

groups (organizations) is a very actual problem of modernity.

Also, one of the most important problems in sustainable city development is road traffic. Optimal routing is perspective direction to solve this problem. Minimizing of path's length reduce fuel consumption and tail pipe emissions of carbon dioxide.

2 Problem analysis and the goal of research

Taxi is an important vehicle in urban transport systems. Encouraging taxi passengers can increase transportation efficiency, reduce overall distance, a time, a congestion and emissions. Today many researchers study the taxi problems. Particular attention is paid to the carpooling and its problems and optimization. The analysis of the most famous publications on the problem of taxi and carpooling allowed to determine the main directions of development of carpooling research and their peculiarities.

S. Ardekani represent a method for carpooling when the driver wages, vehicle operating costs and reasonable compensation of other participants depend on the travel time or the distance based on fuel consumption of the vehicle was proposed [1]. It was a first try to find optimal routers for carpooling problem.

In [2] a static optimal control model with a flexible starting price to satisfy market demand was constructed.

Zou proposed to use a transport network model to calculate the shortest path for a car and analyzed the

* Corresponding author: isugonyak@gmail.com

influence of road factors on the shortest path [3]. Next researcher developed a model for choosing a taxi route and methods of speed optimization based on the principle of fairness, which provides a minimum time of passenger trip and cost as a target function and guarantees a reasonable income of a driver, taking into account the interests of both drivers and passengers. The genetic algorithm was used to solve this problem [4].

M. Friedrich, M. Hartl, C. Magg represent the static and dynamic modes of working with a car, separating the carpooling mode into several types, such as one to one, one to many, and many to many, and developed the path choosing method and speed optimization model, was investigated [6].

In [5] an efficient model of route planning was proposed and a method for solving the problem associated with the taxi management problem was proposed.

M. Tamannaei & I. Irandoost presents a matching algorithm, which works with typical for agent-based technologies integer and non-integer demand occurring in travel macroscopic model. This approach compares two datasets of suppliers and demanders. Optimal path in the road calculated from sequence of links to a sequence of zones [7].

In [7] minimizes the costs of travel times. Branch-and-Bound (B&B) algorithm find optimal solution of the problem. The large-scale problems were solved by near-optimal algorithm. This model tested on real data from transportation network of Isfahan city, Iran.

In [8] authors present a new heuristic, formulated and tested on real-world, and simulated carpooling problem instances, that mimics a decentralized carpool self-organization process. These findings reveal system-wide savings similar to centralized models, and a potential strategy for improving carpool utilization.

The goal of the research was to develop an on-line service oriented for management of non-regular passenger transportation for different categories of users: drivers, passengers and organizations. Service must also resolve the problem of trust between drivers and passengers and implement an algorithm of driver's path optimization.

The defined purpose determines the following tasks:

- research and optimization of taxi tasks;
- construction a model of route optimization for a multi-route taxi;
- building a carpooling club model;
- optimization the driver's route;
- developing a decentralized model of system functioning and the mode of private passenger transportation;
- designing algorithms for the non-regular transportation management system;
- designing the structure of the non-regular transportation management system.

The main results of the on-line service implementation are car amount optimization and minimization path's length – to prevention traffic jam and protect environment in the big city.

3 Optimization for carpooling routes

3.1 Carpooling club model

There are a large number of people who have travel schedules for work enough stable, but there is also a significant and growing number of travels with multiple destinations and directions that tend to not relate work and non-work travels. People who have stable travels can easily create stable groups of cars for carpooling, and we must also take into account the fact that if a person has to go elsewhere than the destination, this must be included in the group route.

The concept of carpooling clubs is to manage both traditional and dynamic systems in one structure, using their compatibility, and also providing a minimum level of trust between their users through filtering and supporting all groups. The traditional flow of groups is the basis of the system, but when free space is appeared within a group, it can be dynamically distributed to random demand by people who normally belong to another flow in the club (Fig. 1). This system is based on users who can act as passengers, as well as drivers. No one is allowed to act solely as a driver or as a passenger; this helps to increase tolerance and avoid criticism.

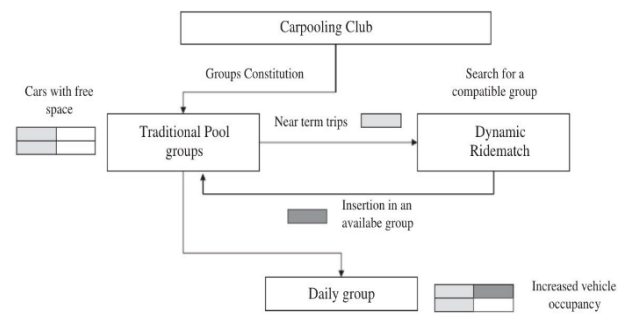

Fig. 1. Carpooling club model.

3.2 Taxi route optimization model

Model conditions:

- Taxi route is independent of the others.
- The capacity of each taxi is 3 passengers.
- Passengers are prohibited from changing the route.
- The taxi speed remains unchanged for carpooling and one-way travel.
- The taxi driver chooses the shortest route.

For a taxi route optimization model, we need to define a target function.

A detour can increase the travel time of passengers in carpooling mode, so a minimum taxi distance can be selected as a target function and optimize the taxi route. The objective function is defined by (1).

$$Z_1 = \sum_{k=1}^n \sum_{i=1}^A \sum_{j=1}^A y_{ij}^k q_{ij}^l d_{ij} \rightarrow \min \quad (1)$$

where $k \in n$, n is a set of taxis; d_{ij} – distance from i and to j ; i and j are adjacent points, $i, j \in A$, A is the number of nodes in the road network; $l \in p$, p is a set of paths for carpooling;

$$y_{ij}^l = \begin{cases} 1 & \text{if carpooling, } ij \in l \\ 0 & \text{if carpooling, } ij \notin l \end{cases}$$

$$q_k^l = \begin{cases} 1 & \text{if } l \text{ carpooling path of the vertex } k \\ 0 & \text{in other cases} \end{cases}$$

After defining the target function for the model, it is also necessary to determine the conditions of the delay restriction.

Carpooling can increase the length of travel for some passengers. For the whole system, total travel distances may not exceed distances when using a standard single-route taxi (2).

$$\sum_{k=1}^n \sum_{l=1}^p \sum_{i=1}^A \sum_{j=1}^A y_{ij}^l q_k^l d_{ij} \leq \sum_{k=1}^N \sum_{L=1}^P \sum_{i=1}^A \sum_{j=1}^A y_{ij}^L q_k^L d_{ij} \quad (2)$$

where $k \in N$, N is a single-way taxi set; $L \in P$, P is a set of single-way taxi routes;

$$y_{ij}^L = \begin{cases} 1 & \text{if taxi with single way route, } ij \in L \\ 1 & \text{if taxi with single way route, } ij \notin L \end{cases}$$

$$q_k^L = \begin{cases} 1 & \text{if } L \text{ taxi path with single way of the vertex } k \\ 0 & \text{in other cases} \end{cases}$$

The restriction of the driver income is also needed to be add to the model. Driver income is another condition that follows from this model. It always exceeds the cost of the travel with the longest distance between the passengers in the taxi (3).

$$r_{ij}^m \sum_m \sum_i \sum_j y_{ij}^l q_k^l q_m^k d_{ij} \geq \max\{c_m q_m^k, \forall m\}, \forall k \quad (3)$$

where $m \in S$, S – the set of passengers.

In the modelling process above, it is assumed that all taxis are traveling with a constant speed. However, since urban transport increases, traffic jams occur, so taxi speed cannot be kept constant at all times. In this case, the target function can be defined by (4).

$$Z_2 = \sum_{k=1}^m \sum_{i=1}^A \sum_{j=1}^A y_{ij}^l q_k^l c_{ij} \rightarrow \min \quad (4)$$

where c_{ij} – the distance from i to j .

The problem of taxi carpooling belongs to the combinatorial optimization problems and to the class of NP-complete tasks, so classical algorithms cannot be used.

Since optimization methods are designed to find the optimal solution that satisfies more than one target function, the concept of optimal Pareto solution is introduced in the theory of optimization tasks to find a compromise solution in multicriteria models. The formal definition of the Pareto optimal solution of the problem is defined as follows

$$\min_{x \in X} (f_1(x), \dots, f_p(x))$$

A valid solution $\tilde{x} \in X$ is called Pareto optimal solution, if there is no other solution such that $f(x) \leq f(\tilde{x})$ for all $k=1, \dots, p$, and at least for one of

them this condition is strictly fulfilled $f_i(x) < f_i(\tilde{x})$, where p is the criteria of evaluation.

Since genetic algorithms proved themselves well as search techniques in large areas with little or no information on the target function properties and constraints, several methods and approaches for using genetic algorithms to solve multicriteria optimization have been developed.

Among representative decision algorithms are the Niched Pareto Genetic Algorithm (NRGA), the Non-dominated Sorting Genetic Algorithm (NSGA-II), and the Strength Pareto Evolutionary Algorithm (SPEA2). All these algorithms have favorable solution efficiency in a particular problem.

The multi-criteria genetic algorithm should obtain the maximum approximation of the set of solutions found to the true Pareto front, at the same time preserving and stimulating the variety of the solutions found, in order to completely obtain the entire Pareto front.

On the flowchart of the algorithm (Fig. 2), Pop represents the population, and Pop is the scale of the population expressed by A . Paretos is the optimal Pareto solution, where Paretos is the number of optimal Pareto solutions in the set of solutions, which is expressed by B . The final conditions have certain restrictions.

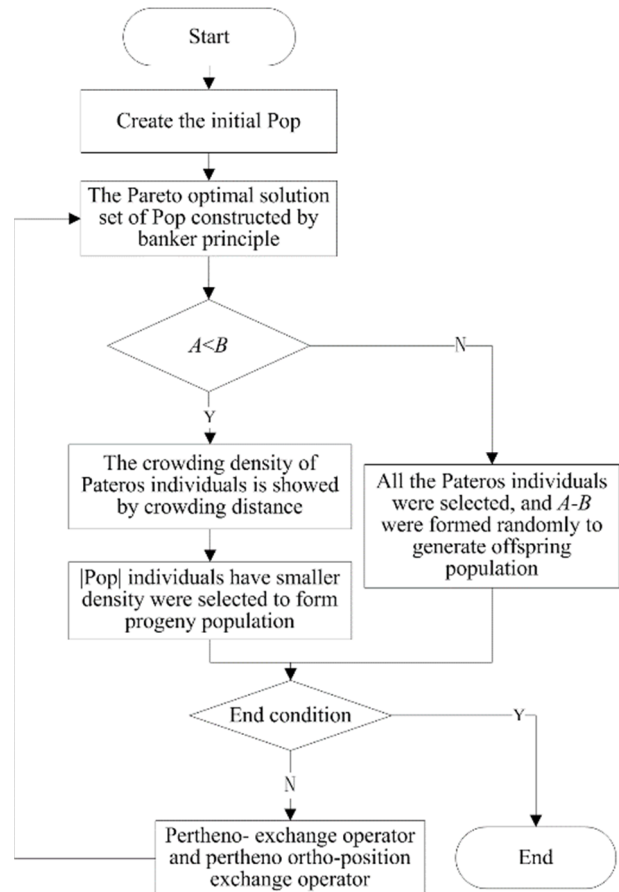

Fig. 2. Block diagram of the algorithm.

4 Design and implementation of separate modules of the system

4.1 Optimizing the driver path

In order to save fuel and a driver time, it is necessary to build the optimal route to be followed by the driver during the passenger transportation. Since an order may contain several destinations, it is possible to describe a model as a graph $G(V, E)$, where the points of destination and a driver location will be the set of vertices (V), and the shortest distances between all vertices will be the set of edges (E). The shortest distances between any two vertices can be obtained by using Google Maps API.

It must also be stated that the shortest distance from vertex A to vertex B will not always be equivalent to shortest distance from vertex B to vertex A (shortest_dist($A \rightarrow B$) \neq shortest_dist($B \rightarrow A$)), so the graph can have two edges from each vertex to each and should be oriented.

The solution of this problem can be the shortest closed route that passes through all the vertices of the graph exactly one time. In such formulation the problem of the optimal route for the driver is reduced to solving the asymmetric salesman problem. Since the problem is expressed by an oriented graph, it is asymmetric, so there $(n-1)!$ possible routes exist.

Since the problem of finding the optimal route where can be no large dimension is necessary to solve, it is suggested to use one of the exact algorithms, the Little's algorithm.

If we take the driver destination and location as the vertices of the oriented graph $G(V, E)$, and the shortest distances between them as the graph arcs, and impose an additional acyclic condition for the previously set task, the problem of the optimal driver route with no need to return to the starting point can be reduced to a closed variant of the salesman problem (see Fig. 3).

The unclosed variant of the salesman problem is reduced to the closed one by changing the weights of arcs that enter to the start vertex with 0. The optimal closed route of a salesman in such graph corresponds to the optimal closed route of the outgoing graph.

The minimum acyclic Hamilton route, which will begin at the starting point and pass through all destinations, specified by the client exactly once, will be the solution of this problem.

Following such a route, the driver will be able to fulfill the client order for minimal time without returning to the starting point. However, it is often necessary to visit one destination $A(0)$ first (start stop) and another destination $A(n-1)$ last (end stop) among the n certain destinations. In this case, the points between $A(0)$ and $A(n-1)$ should be visited in the most optimal order. Solving a previously set task will not satisfy the conditions of the new task.

As in the previous case, it is possible to formulate a new problem using the oriented graph $G(V, E)$, where the set of all client destinations is the set of vertices V , and the set of shortest distances between each location is the set of arcs E . In this case the location of the driver does

not need to be specified in the problem, since his first path will always be the path to the starting point, assigned by the client. After that he will need to follow the route, which will be the solution of the problem. And a minimal acyclic Hamilton route that starts strictly at a point A (client-assigned starting point) and ends at a point Z (client-assigned end point) will be the solution (Fig. 3).

Fig. 3. The minimal acyclic Hamiltonian route, which starts at a given point and ends at the last one.

Since the route must be acyclic and begin and end at the certain vertices A and T correspondingly, the problem can be reduced to the closed salesman problem by adding a new vertex $V(n)$ into the graph. In this case, all arcs leading to vertex $V(n)$, except the arc from the vertex T , must be assigned a weight greater than any possible distance of any Hamiltonian route of the original graph. The arc from the vertex T must be assigned with the weight of 0. This is required to ensure that there is a guaranteed path from the vertex T to the vertex $V(n)$ in the result. Since, if in the cycle obtained during the of solution the vertex $V(n)$ with its edges is rejected, then the vertex T becomes the last in the optimal non-closed Hamiltonian route.

All the arcs coming out of the vertex $V(n)$, except the arc, that enters the vertex A , must have a weight greater than any possible distance of any Hamiltonian route of the original graph. The arc that enters the vertex A must be set its weight to zero. This is required in order to guarantee a path from the vertex $V(n)$ to the vertex A . As a result, if in the cycle obtained during the of solution, the vertex $V(n)$ with its edges is rejected, then the vertex A becomes the first in the optimal non-closed Hamiltonian route.

Based on the research, a problem was set, the solution of which completely satisfies the purpose of the work. This is a problem of minimal acyclic Hamiltonian path that begins at a given point and ends at the last one (see Fig. 3), which can be reduced to a non-closed asymmetric task. Since the solution of this problem is the optimal route, which begins at the first client-assigned point and ends at the point of the last destination in the client order, the given solution completely satisfies our purpose - to find an optimal route for the driver.

4.2 Designing algorithms for the non-regular transportation management system

As the geoformation management system for non-regular passenger transportation is oriented to two types of actors: drivers and passengers, the logic of processing orders, work with other actors and the map was separated on the corresponding modules. Among the main modules

in the system are the module for constructing and displaying the route of the user, the module for creating orders, the module for sending orders and managing them and the module for working with organizations.

All algorithms of the system were implemented in JavaScript language with using the additional libraries. The Google Maps API service was used for geocoding, reverse geocoding and for finding and constructing the shortest path between two specified addresses. The calculations of distance and cost are performed by a separate module based on a path built with the help of Google Maps API.

The algorithm of optimal driver path was obtained by the way of reducing the optimal path problem with fixed start and end points to the salesman problem. The algorithm for solving the salesman problem was implemented using the Little method. Using of Little's algorithm with Google Maps traffic jam detection technologies should reduce fuel consumption more than 30%.

4.3 Designing the structure of the non-regular transportation management system

An event-oriented approach for development was used using RAM cache based on Redis and using Sosket.io for sending notifications.

The non-regular passenger transportation management service (Fig. 4) physically is composed of a Web API service component and a client single page application that can be deployed with server-less architecture. The client part is not required a server to deploy. Amazon S3 or similar by the functionality platforms for the static content is sufficient to use.

To deploy a smartphone client application, corresponding package is required to install. Structural diagram of the system is shown in Fig. 5.

The business logic of the application is implemented in JavaScript programming language. A monk framework was used for work with MongoDB database. Each collection was built with a wrapper that provides a convenient interface for working with MongoDB.

Redis was used to cache orders, store Sockets.io customer IDs and other operations requiring quick access. To work with Redis on NodeJS, corresponding library node-redis was used, and an additional wrapper was implemented to adapt methods to the system.

To work with Web-sockets Socket.io library was used and a number of classes were written to handle events and send messages. The ConnectionHandler class is responsible for connecting and disconnecting users which open or close an application.

5 The results of the research

After the successful login, the user will see the main page. In driver mode, he will see a map with the locations of other drivers and a block displaying the current active orders from the clients (see Fig. 6).

If the driver mode is switched off, the user will see a page with a map, locations of the active drivers and a

block for building the path for his or her order.

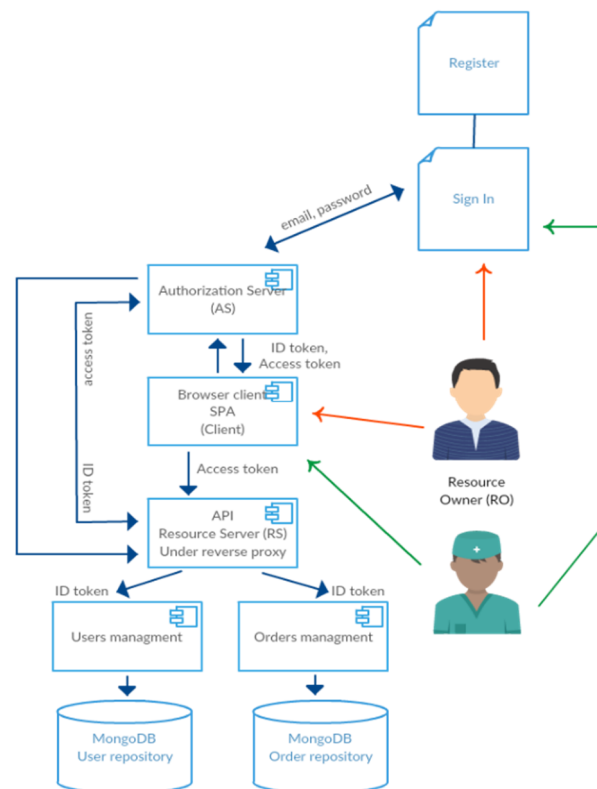

Fig. 4. System services interaction scheme.

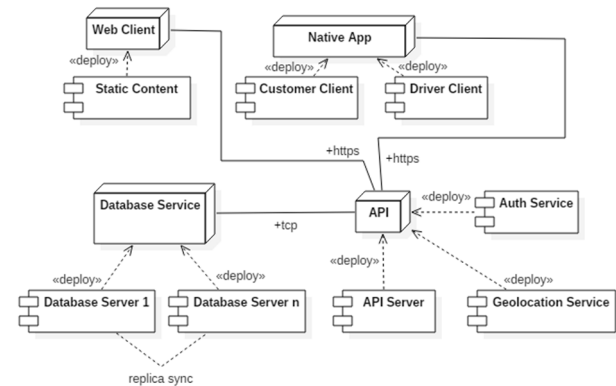

Fig. 5. Structural diagram of the system.

Passengers also have an option to optimize their route and build the shortest possible path. To do this the option “Shortest route” must be selected.

Once the order is created, it is sent to all drivers online, the drivers have 60 seconds to accept the order or decline it. After the first driver accepts the order, it becomes disable for all other drivers, and the passenger will be notified about the accepted order. The passenger must choose: to agree or to refuse to go with the driver who accepted the order. If the passenger agrees to go with the driver – the driver will receive a message about the confirmed order (Fig. 7) and has to go to passenger. Otherwise the driver will receive a rejection message, and all other drivers will again be able to accept the order.

After the order has been completed, the driver confirms its completion and optionally may write a

review of the passenger and evaluate him. The passengers have similar functions. Later the driver and the passenger may again create and accept new orders.

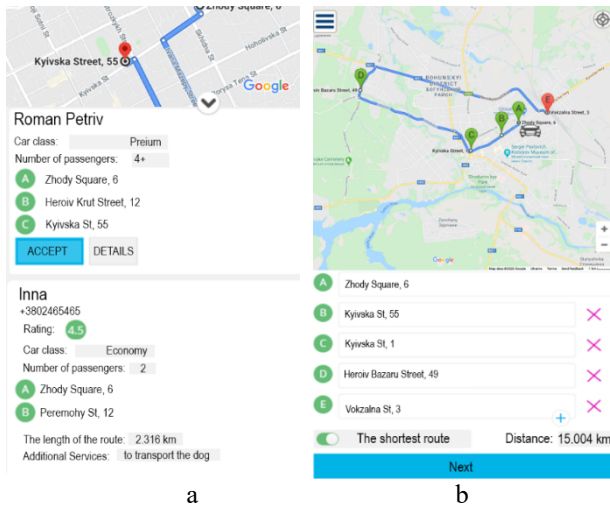

Fig. 6. Main page (a) for the driver and (b) for the passenger with the built path.

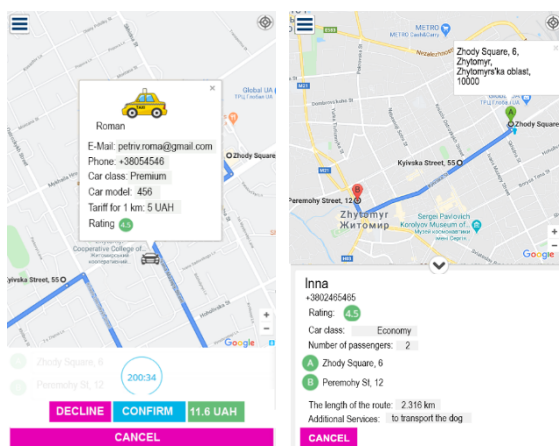

Fig. 7. The order received by the driver and the process of confirmation.

According to the results of the load testing, the service is able to support a large number of users while consuming a small amount of resources. As a result of the security testing, no critical vulnerabilities were identified, and measures were taken to protect against the most common attacks.

6 Conclusions

The passenger transportation management service was designed and implemented in the work.

To solve the set problem, a number of services for performing some useful for the work functions were analyzed.

The main functions of the service are building of paths on the map in real time, the modes of the driver and the passenger, the calculation of the length and the cost of the route, the creation of organizations and private modes of the work.

For implementation of fault-tolerant, highly accessible, reliable and scalable system, a number of technologies were analyzed and those that maximally correspond the specifics of the system functioning were selected. The document-oriented MongoDB was used as the database. To optimize data processing speed, data caching was used using Redis. The client and server code were written in JavaScript programming language. Working with Web-sockets is one of the most important functions of the system. Socket.io library was used for this purpose. The system is based on event-oriented architecture, which provides additional advantage in the resources use.

Algorithms for service functioning were developed and Goggle Maps API was used to implement some of the algorithms for building routes and geocoding.

This system should have positive impact to environment, because optimal transport routers minimize tail pipe emissions of carbon dioxide more than 5%.

Application of soft sensors in the automated process control of different industries

Oleksandr Savytskyi, Maksym Tymoshenko, Oleksandr Hramm, and Serhii Romanov*

Kryvyi Rih National University, Department of Automation, Computer Science and Technology, Kryvyi Rih, 50027, Ukraine

Abstract. Sustainable development of industry is closely related with tries to automate industrial processes in all possible ways. Recent advances in automated control systems have led to decreasing the cost of hardware and energy consumption. This article describes examples of soft sensors using in various industries. The main advantages of soft sensors are low cost, flexibility and versatility. In addition, the soft sensors are environmentally friendly as they significantly reduce the amount of equipment and do not require utilization. Despite these benefits, there are some problems with using them. First problem consists in what information and how needs to be measured to use received data in calculation of another virtual data. Second problem is using proper software and the time of mathematical calculations. The goal of the soft sensors is generation of valid virtual data for the controller to increase the accuracy and quality of the automated control. The article is of interest from the point of view of possibilities to applicate modern technology in solving various tasks of automated control.

1 The rationalisation of using soft sensors in the automated control of industrial sites

Increasingly, industrial enterprises are demanding improved production efficiency, following government laws that apply strict restrictions on product specifications and pollutant emissions, leading to increasingly effective measurement and control policies. In the context of the sustainable development of industrial process control, the importance of monitoring a large set of processes variables with the help of adequate measuring instruments is clear. However, the key obstacle to implementing a large-scale monitoring and control policy is the high cost of online meters [1-3].

Mathematical process models based on experimental data, through systematic identification procedures, can greatly help to reduce the need for measuring instruments and to develop a rigid management policy. Mathematical models designed for the aforementioned purposes are known as virtual analysers or soft sensors.

Soft sensors are a valuable tool in many industries, including oil refineries, chemical plants, cement kilns, power plants, pulp and paper industries, food processing, nuclear power plants, urban and industrial pollution monitoring. They are used to solve a number of different problems, such as backup system measurement, “what to do” analysis, real-time forecasting for installation monitoring, sensor testing, and fault diagnosis strategies.

Industries are faced with the choice of an appropriate production policy, which is the result of trade-offs number among various constraints. Final product prices and quality are, of course, two relevant and competing

factors that can determine an industry’s market success. Closely related to such aspects are topics such as energy and raw materials consumption, especially due to the ever-increasing prices for energy resources. Moreover, compliance with safety rules (according to several studies, inadequate management of emergencies is the main cause of industrial losses) and environmental pollution problems add to the complexity of the scenario.

Unfortunately, measuring instruments are generally required to operate in adverse or extreme conditions, which on the one hand requires instruments to meet very limited design standards, while a maintenance protocol must be planned on the other. In any case, the occurrence of unexpected faults cannot be completely avoided. However, some measurement tools can introduce significant delays in application, which may reduce control efficiency. Setting up and maintaining a large-scale metering network is never cheap, and the budget you need can significantly affect the total running costs of the plant, which are usually biased to reduce the total number of variables and/or frequency of observations, although in many industrial situations infrequent sampling (lack of online sensors) of some variable processes can present potential performance issues. The typical case is that product quality variables are determined by offline analysis of samples in the laboratory, thus creating a gap and significant delays [4-6].

Soft sensors offer a number of attractive features:

- they are an inexpensive alternative to expensive hardware devices, allowing for more comprehensive monitoring networks;

* Corresponding author: tymoshenkomaxym@gmail.com

- they can work in parallel with hardware sensors, providing useful information for troubleshooting tasks, thereby allowing for more robust processes to be implemented;
- they can be easily implemented on existing hardware (such as microcontrollers) and restored when system settings change;
- they allow you to evaluate data in real time, overcoming the time delays introduced by slow hardware sensors (such as gas chromatographs), thereby improving the effectiveness of control strategies.

There are three basic approaches to building soft sensors: mechanistic modeling (physical modeling), multivariate statistics, and artificial intelligence modeling using neural networks, fuzzy logic, and hybrid methods or algorithms. This classification approach does not have to be very rigid, and techniques specific to one approach are often refined using techniques typical of others.

Appropriate empirical models or data-driven models that generate reliable estimates of real-time process variables based on their correlation with other relevant system variables can be useful tools in industrial applications due to the complexity of installation dynamics, which necessitates the use of soft sensors methods and tools.

Let's consider some examples of soft sensors application by well-known scientists are engaged in the research and implementation of soft sensor technology in automated control systems.

In the article [7] use of soft sensors for the estimation of pollutants in the output flow of a Sour Water Stripping plant in Italy is described. The soft sensors have been implemented by nonlinear data-driven approaches with use of deep learning. The deep learning approach allowed for exploiting all recorded historical data, solving the typical problem of data scarcity. As a result, soft sensors based on neural networks were developed and implemented in the enterprise.

The paper [8] introduces a soft sensor for the estimation of the deflection of a polymeric mechanical actuator. The actuator is based on ionic polymer-metal composites (IPMCs). Applications of IPMCs have been proposed in fields such as robotics, surgery, and aerospace. In such application fields, both the size of the actuating system and the complexity are of chief importance. A soft sensor can be preferred to hardware measuring the actuator output, for estimating the actuator motion. Also, low-order models are of interest to limit the computational load, which can be a constraint in real-time applications. To this aim, several data-driven nonlinear finite-impulse response models have been investigated.

The paper [9] describes an interesting approach for designing a data-driven soft sensor for a plant, in the presence of an unknown measurement delay. For the realisation are used deep belief networks. The features, obtained after the unsupervised learning phase, are exploited for estimating the measurement delay. The procedure is applied to the design of a soft sensor for a debutanizer, which is a part of a refinery settled in Sicily.

The paper [10] analyzes a number of strategies that are devoted to improving the generalization capabilities of neural-network-based soft sensors when only small data sets are available. Authors searched for a strategy that is able to cope with the problem of scarcity of experimental data, which often arises in industrial applications. The methods considered were compared in an industrial case study regarding the design of a backup soft sensor for a thermal cracking unit, working in a refinery plant.

In the paper [11] the soft sensor design strategy for an industrial process, via neural NMA model, is described. In details, the hydrogen sulphide in the tail stream of a Sulfur Recovery Unit of a refinery located in Sicily, Italy, is estimated by a soft sensor. It is based on the minimization of the Lipschitz numbers by a Genetic Algorithms approach. A comparative analysis with an empirical model, developed on the basis of suggestions given by plant experts, is included to show the validity of the proposed procedure.

As can be seen, soft sensors are used in different types of industry and are built using different mathematical mechanisms. The following chapters of article discuss in more detail examples of the soft sensors use by the authors in energy management, the automation of iron ore enrichment processes, and the management of alternative energy sources.

2 Application of soft sensors in the automated control of iron ore enrichment processes

2.1 The complexity of controlling the process of loading the mill with iron ore

Iron ore grinding is a preparatory process for magnetic ore enrichment. Magnetic separation is the main process of magnetizing factories. According to the sustainable development principles in mining and processing it is necessary to build and control systems of magnet-processing factories technological complexes. The pilot or conductive control object is a magnetic separator, and the driven one is a drum mill, the task of which is to open the spores of a useful mineral with an empty rock. The possible degree of ore opening is determined by the nature and size of the grain entrapment. For example, the source iron ore supplied for grinding, classification and magnetic separation is substantially heterogeneous in its chemical composition and texture and structural properties, even within the same deposit. For example, the Ingulets deposit of the Kryvyi Rih iron ore basin is represented by four types of ores: heavily enriched, consisting of carbonate-magnetite and silicate-magnetite quartzites (magnitude of magnetite incorporation 0.008-0.08 mm); medium enriched crushed, consisting of magnetite-silicate and carbonate silicate-magnetite quartzites (magnitude of magnetite incorporation of 0.02-0.2 mm); medium-enriched light-crushed, consisting of red-gray-magnetite silicate and silicate-magnetite quartzites medium and broad-banded (magnitude of 0.02-0.07 mm inclusions); light enriched,

consisting of silicate-magnetite and magneto-silicate quartzites (magnitude of magnetite incorporation of 0.02-0.1 mm). Variables are also the strength of the ore and its density, as well as the mineral composition: magnetite, martite, hematite, iron hydroxide, siderite, sulfides, quartz, silicates, etc.

The main methods of ore preparation at the magnetic concentrating factories are grinding and classification in order to control the particle size distribution of the ore supplied to the magnetic enrichment. Given the uneven composition and variable properties of the ore, there is a need to control the grinding process in order to achieve the optimum size of ore grinding and to obtain the optimal fractional composition of raw materials fed to the magnetic separation.

From the point of view of grinding, the main adjustable variable of the drum mills is the loading or filling the mills with ore, which determines the size of the grinding product at the output of the units. The grinding size significantly depends on the initial enrichment. For example, in the dependences of iron content in concentrate β and the extraction of iron in concentrate ε are presented, depending on the size of grinding (Figure 1).

Fig. 1. Dependences of magnetic enrichment indicators according to V. V. Karmazin: ε – extraction; β is the iron content.

The analysis of these dependences shows that there is an optimal size of the mineral opening corresponding to the maximum values of ε and β .

The magnetic separator clearly responds to the fractional composition of the mineral raw material (Figure 2). If the raw material is undergrinded, then the iron yield and content in the concentrate will be less than with well-exposed mineral raw materials. Conversely, if the raw material is overgrinded, the content of iron in the tails will increase, the yield of the concentrate will also decrease.

Thus, a magnetic separator is a natural indicator of grinding results. The optimal size of grinding ore will correspond to the optimum magnetic enrichment.

Therefore, the criterion for optimal loading of the drum mill is the maximum performance of the pilot magnetic separator for the magnetic product.

There is a known relationship between the active power consumed by a magnetic separator motor and the separator performance by a magnetic product. So, the criterion for optimal loading of the ore drum mill is the

maximum value of the active power of the magnetic separator drum motor.

Fig. 2. Enrichment curve for good (1) and bad (2) grinded ore

2.2 Application of soft sensors for automatic control of ore loading process

In order to develop algorithms for the optimization of technological complexes of magnetic ore enrichment with ball mills and milling machines, it is necessary to know the static characteristics of these complexes.

A mathematical model of the technological complex of magnetic enrichment of the first stage (Figure 3) was compiled.

Symbols of Figure 3 have description: φ_p – degree of loading mill with iron ore; P_S – active power of the separator motor; P_M – active power of the mill motor, γ_p – pulp density in the mill.

As a result of the simulation, a static characteristic of the technological complex was obtained (Figure 4).

The analysis of this characteristic shows that to the maximum productivity of the complex in the magnetic product, the active capacities consumed by the mill P_M and the separator P_S are unidirectional, that is, with increasing degree of mill loading with ore they increase. Further increase of loading degree leads to a decrease in the active power consumed by the separators P_S , and accordingly the productivity of the complex by the magnetic product, while the power consumed by the drive engine of the mill increases.

Similarly, the static characteristics of the technological complex of magnetic enrichment with a ball mill of (Figure 5) were obtained.

During the study, it was assumed that the overflow's density of the classifier was stabilized by an automatic density control system at 1400 g/l.

On Figure 4 the following designations are accepted: 1 – large interspersed ore; 2 – medium interspersed ore; 3 – little interspersed ore.

On Figure 5 the following designations are accepted: 1 – 40 t ball load; 2 – 45 t ball load; 3 – 50 ton ball load.

The degree of the ore mill loading φ was measured and stabilized at a predetermined level using a radioisotope fill indicator and a mill loading control system. During each experiment, to collect the

experimental data, the laboratory of the Pivnichnyi GZK (Kryvyi Rih Northern Mining and Processing Plant) selected technological samples of industrial products and tails, performed their chemical analysis of the iron content and determined the volumetric productivity of the separator on the products by measuring capacity and stopwatch, as well as the productivity of the complex by magnitude Q_M . At the same time, readings of measuring instruments of the drive motor active power of the mill P_M and the drive motor active power of the group of magnetic separators of the first stage P_S were recorded. The regression equation was obtained

$$P_S = 16.7 + 3.27Q_M \quad (1)$$

which confirms the possibility of measuring the performance of the technological complex by magnetic iron Q_M by the amount of active power consumed by a group of magnetic separators. According to the results of

the experiment, the energy consumption per ton of the obtained magnetic product was simulated. The correlation coefficient between the variables Q_M and P_S was 0.89.

Since the active power consumed by magnetic separators, P_S is proportional to the performance of the complex over magnetic iron Q_M , then the maxima of static characteristics $Q_M = f(\varphi)$ and $P_S = f(\varphi)$ must coincide. Therefore, an increase in the degree of loading of the ore mill φ leads to an increase in the active power P_S consumed by the magnetic separators and the active power P_M consumed by the mill. Further increase in the degree of mill loading with ore leads to a decrease in the performance of the complex on the magnetic product Q_M and, accordingly, consumed active power P_S by the separators, while the power P_M consumed by the drive engine of the mill, increases.

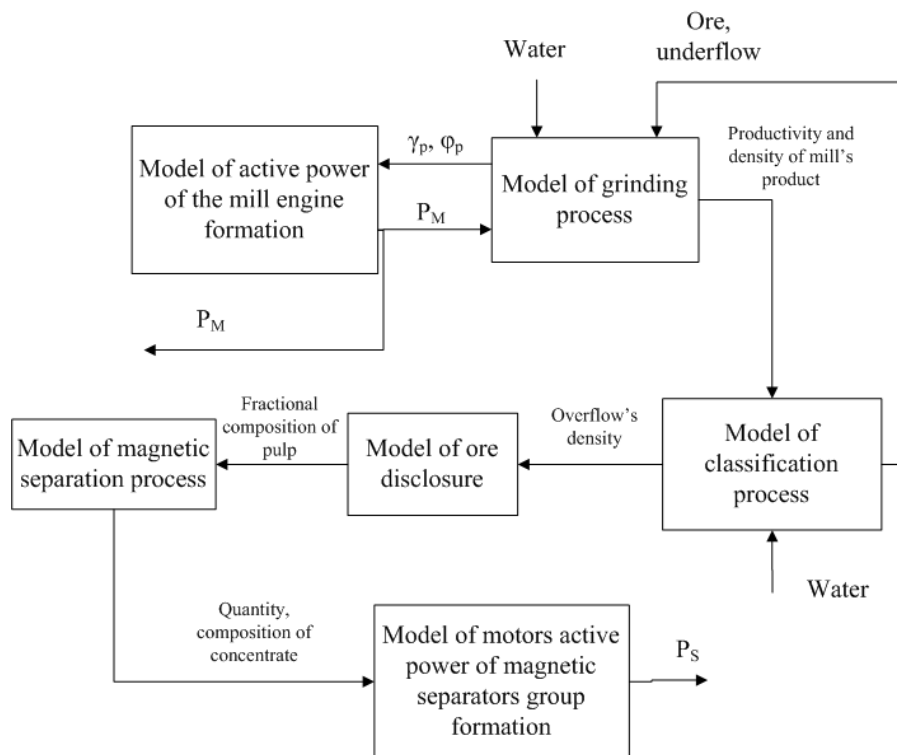

Fig. 3. Scheme of the model of information transfer between mechanisms on the course of the technological complex of magnetic enrichment.

Fig. 4. Static characteristics of a technological complex of magnetic enrichment with a mill of wet selfgrinding.

Fig. 5. Static characteristics of the technological complex of magnetic enrichment with a ball mill.

The conducted researches confirm that it is advisable to use soft sensors to control the process of loading the mill with iron ore, namely to control the degree of the mill loading with ore, given the active power of the magnetic separator motor.

3 Using of soft sensors in the automated control of solar power plants

In any real system, such as a solar power plant, a data collection system must be put in place to monitor performance, which provides monitoring of the parameters that are important to the system. There are many methods that use classic hardware to collect and transmit data, but in large solar power plant, this can be quite expensive due to the large amount of sensors required and therefore impractical to implement. In solar plants, such controlled parameters are the output power, voltage and current at the panel output, its temperature, and in the case of solar tracking systems – the angle of inclination to the horizon and the angle of rotation of the panel. Such a system has a complex relationship between all parameters, and therefore the technique of obtaining one or more variables from another measured value can be applied. That is why the use of virtual sensors, or so called soft sensors, is most appropriate in terms of reducing the amount of equipment needed and, as a consequence, its cost.

However, this is not the only one property of soft sensors. If there is already a sufficient set of equipment and sensors in the solar power plant, the use of virtual sensors can improve control accuracy. Sometimes, the sampling rate of real sensors is not high enough, which does not match the capabilities of the controllers. Therefore, by increasing the amount of data received by the controller, it can be improved: the controller receives a signal from real sensors every T seconds, and additionally, from virtual sensors every $T/5$ seconds. This method, in which the data processing speed of the controller is N times greater than the actual sensor sampling period, is called multi-rate. And at times when real-world sensors can't get information due to certain unforeseen circumstances, soft-sensor information allows the controller to continue its control task at the normal level, the effects of missing information are minimized.

The block diagram of the system using the soft sensor based on a mathematical model of a multi-rate process is shown in Figure 6. In this system, the soft sensor works in parallel with the real sensor, and in real-time receives data from it and additionally receives a control signal coming from the controller to the actuator. The advantage is that the effects of delay in the transmission of the control signal and the sampling rate of the real sensor on the real process are taken into account in the virtual environment, providing more reliable virtual data from the soft sensor.

Fig. 6. Block diagram of a soft sensor control system.

According to Figure 6, the multi-rate controller uses virtual data obtained from a soft sensor based on the process model to calculate additional control actions sent to the actuator. Thus, the triggering process is faster than the actual sampling rate of real sensors, overcoming the problem of limiting the sampling rate of those sensors.

As noted above, we are considering the implementation of soft sensors for a solar power plant. One of the most important parameters of this system is

the maximum power of the generated electricity. Maximum power point tracking is a must to maximize the efficiency of converting solar energy to electricity using solar panels. Directly the power is affected by the amount of solar irradiance per 1 m² of solar field: the more solar energy, the greater the output power of the system; and partial shading dramatically reduces the amount of electricity. Therefore, it is important to receive timely data on the level of solar irradiation to

adjust the position of solar panels. Complex instruments such as pyranometers or pyrhemometers are used to determine the amount of solar radiation per unit area. But their cost is too high to install many sensors across the entire solar power plant. The maximum power of the solar panel directly depends on the performance ratio PR :

$$PR = \frac{P_i}{P_{nom}} \frac{G_{STC}}{G_i} \quad (2)$$

where, P_i – measured instantaneous power, P_{nom} – nominal power of the panel, G_i – actual instantaneous level of solar radiation, G_{STC} – solar radiation under normal conditions. Almost all of the values in the (2) are known: the nominal power is given in the solar panel technical data sheet, the instantaneous power can be measured by multiplying the voltage U_i and the current I_i at the output of the panel, and solar radiation under normal conditions can be obtained from the statistics from the geographical location of the solar power plant. The amount of solar radiation that falls into the panel at the moment can be calculated from formula (2):

$$G_i = \frac{P_i}{P_{nom}} \frac{G_{STC}}{PR} \quad (3)$$

where, PR is applied as coefficient of 0.6–0.8 as for normal panels functioning.

In this way, the soft sensor will calculate the instantaneous solar radiation for the panel positioning system relative to the sun to possibly increase the electricity generated and improve the efficiency of the solar power plant. And in the case of dividing a large field of several hundred or thousands of solar panels into separate sections, calculate the solar radiation for each of them to position these areas independently of each other, to minimize the effects of partial shading of the panels by clouds.

4 Soft sensors using approach in industrial reactive energy measuring

Sustainable development of industry is associated with increasing requirements for the quality of the supplied electric energy. Moreover, a very important factor is the ability to accurately measure the power flowing in the network at any level. This is important for both suppliers and consumers of energy. With increasing productivity and improving the quality of finished products of industrial enterprises, their consumption of energy resources also grows. At the same time, the requirements for the capacity of the power lines of these objects are increasing. The observed trend of a significant increase in the share of non-linear and non-stationary loads in power networks leads to a reduction in the throughput of these distribution networks due to an increase in the reactive capacities flowing in them. This problem is associated with the increasing use of power electronics devices among other consumers of electric energy. Examples of such devices include induction furnaces and heaters, gas discharge lamps, variable speed drives, etc.

The growth of reactive power flowing in the enterprise network creates a large amount of interference for the enterprise itself and adversely affects the entire distribution network. Also, the fact that such consumers are becoming generally accepted leads to the fact that the equipment on the consumer side and on the side of the electric energy suppliers operates in non-sinusoidal signal modes, which adversely affects the accuracy of measuring instruments. And in conjunction with the growth of reactive power flowing in the network, it leads to an increase in losses during the transportation of electric energy and a decrease in the power factor of consumers. The measurement and control of the adequacy of the reactive power measurement system is associated with a set of problems, including the high cost of such a system for large industrial facilities, such as mining and processing plants, because of their distributed structure and the supply of different structural units of such an object to different power lines from different distribution substations. In such a situation, as a possible solution to this problem, we can consider the analytical calculation of reactive power volumes through other simply measured parameters of the distribution network. So when considering the distribution system of electric energy and the nature of the loads connected to it as linear and operating exclusively in the mode of sinusoidal signals, the reactive power is determined by a simple ratio:

$$Q = U \times I \times \sin\varphi \quad (4)$$

Where: I is the effective value of the current strength in the network; U is the effective voltage value in the network; φ is the phase difference between current and voltage.

When considering the operation mode of the system under the influence of non-harmonic signals, the effective values of voltage and current in the network can be expressed as:

$$I = \sum_{k=1}^K I_k \sin(2\pi k f_0 t - \psi_k) \quad (5)$$

$$U = \sum_{k=1}^K U_k \sin(2\pi k f_0 t - \theta_k) \quad (6)$$

Where: k is the harmonic number of the sinusoidal signal of frequency f_0 ; I_k is the effective current value of the k harmonic; U_k is the effective voltage value of the k harmonic; ψ_k and θ_k are the initial phases of the signals; K is the total number of harmonics considered.

As can be seen from the above expressions, the analytical solution to the problem posed is associated with an even greater number of difficulties due to the large number of additional difficult to measure quantities. Based on this, it seems logical to use soft sensors for calculating reactive power. Let us consider as an object the mining and processing plant mentioned above. We make the assumption that, within the framework of one distribution substation, the consumption of reactive power by each structural element of the object affects the consumption of the others. In this case, the structural element with the largest volumes of reactive energy consumption should have the greatest influence. To verify this assumption,

we use statistics on the consumption of reactive energy of the mining and processing plant. There are statistical data on the consumption of reactive energy by the four structural elements of the facility, which are supplied with electrical energy from one distribution substation. A fragment of statistical data on the consumption of reactive power by four structural elements of an object with a measurement frequency of two hours during one day is given in the Table 1.

For a complete set of available statistical data, we will calculate the correlation coefficient of the reactive power consumption of the structural element with the highest consumption of other structural elements. The calculation was carried out according to statistical data for 7 calendar days. The result obtained in the form of correlation coefficients of reactive power consumption by objects 2-4 with object 1 for a period of 7 days is displayed in the Table 2.

Table 1. Statistical data of mining and processing plant reactive power consumption.

Time, h	Obj. 1, kvar*h	Obj. 2, kvar*h	Obj. 3, kvar*h	Obj. 4, kvar*h
02:00	14348	46	102	972
04:00	13218	45	53	912
06:00	14649	47	102	912
08:00	14471	49	106	792
10:00	13771	50	101	80
12:00	11534	48	96	804
14:00	12790	43	127	1020
16:00	13077	48	98	1224
18:00	12552	43	98	804
20:00	12344	5	119	996
22:00	13760	5	94	888
24:00	12400	6	95	732

Table 2. Correlations coefficients of structural elements reactive power consumption

Day	Element 2	Element 3	Element 4
1	0,569	0,303	0,659
2	0,741	0,469	0,897
3	0,433	0,498	0,965
4	0,565	0,443	0,759
5	0,728	0,248	0,903
6	0,715	0,645	0,796
7	0,638	0,459	0,956

From the obtained correlation coefficients, we can conclude that the initial statement about the relationship between reactive power consumption by the structural elements of the mining and processing plant within the boundaries of one distribution substation is correct, and the obtained data can be used to further search for mathematical patterns and develop a soft sensor to predict the reactive power consumption value of all structural objects of the mining and processing plant that are supplied with electrical energy from one distribution substation based on the value of reactive power consumption of one of these elements.

5 Analyse of obtained results

The analysis of soft sensors using in the automated control of various industrial processes shows their versatility and benefits. The use of soft sensors is often a more viable alternative to hardware, as very often physical sensors have to operate in extreme conditions, are quite expensive and need frequent replacement. It is advisable to use soft sensors in the case of a large number of similar mechanisms operating in approximately the same conditions. Measuring certain performance of one mechanism, you can roughly judge the situation as a whole.

Unlike sensors made from various material substances, soft sensors have a different basis. By definition, "soft sensors" are based on the use of software and the calculation of regulated process parameters. Thus, the environmental friendliness of their use is not in doubt.

At the same time, it is not necessary to check such sensors for the content of harmful substances and hazardous emissions during their operation. At the end of their life cycle, one does not have to worry about compulsory utilization.

As for the status of a sustainable product, the application of software solutions has a long-term perspective on sustainable development.

Soft sensors can be built on different technologies. These can be physical implementations that combine several heterogeneous primary and secondary converters in their design. But more often, soft sensors are modelled virtually on the basis of mathematical devices of fuzzy logic, neural networks, adaptive systems, etc. The choice of mathematical apparatus depends entirely on the specific situation and the specific task.

The main difficulty in working with the principles of soft sensors is lack of knowledge about them due to their novelty and, as a consequence, the lack of conventional mathematical descriptions or structure. On the other hand, it opens up opportunities for creativity.

In general, to work with soft sensors it is necessary to have large arrays of statistics for calculations. It is necessary to have a good understanding of the controlled process principles, physical features and find correlation between the parameters.

The review results suggest that the soft sensor instruments can significantly reduce the amount of mechanical equipment and, through calculated correlation dependencies, delegate the task of measuring certain process parameters to software.

Zhytomyr Polytechnic State University, Department of Automation and Computer-Integrated Technologies, Zhytomyr, Ukraine

Abstract. The task of achieving greater flexibility and maneuverability of small transport and service units' motion in modern factories by developing small autonomous navigation systems plays crucial role in complex automation of transport logistics nowadays. To solve navigation task, it was proposed the following approach, where as a means of assessing the environment was used computer vision system based on 5-megapixel CMOS image sensor and for the front obstacle detection was used auxiliary ultrasonic sensor as a limit switch. Authors solved the problem of yawing using artificial marking approach as along two-colored leading lines. For maneuverability increase during the turn was used speed movement control based on lines perspective. The basic design and technical characteristics of the four-wheel drive platform and the algorithm of the Raspberry PI 3/Arduino Nano hybrid control system are presented. Experimental results proved the viability of the proposed approach.

1 Introduction

According to last report of Grand View Research company [1], the global Automated Guided Vehicle (AGV) market is dynamically growing. This is thanks to the rising demand of automation systems based on computer vision technology. This type of systems has found wide application in transport logistics, assembly, packaging and storage facilities. The automotive, food, aerospace, pharmaceuticals and retail sectors most of all need this technology to make the service operation process safer for personal and other co-operating technological equipment. AGV gives ability to increase productivity and minimize operational costs by using Industrial 4.0 technologies workspace organization [2]. The automation equipment offers a number of classic and innovative solutions to reach high flexibility with approved cost-effective techniques in implementation. In addition to large systems such as robot platforms, small transport and service units are capable to perform path observation, complete simple operations as monitoring and, in some cases, can be combined into a cluster to increase the availability by spatial configuration with one or several control units.

Rapid development of computer systems and workspace recognition techniques, together with the increase of units' number working together and the decrease of their cost, stimulate research of new and combined solutions based on the available hardware and software systems. Smart sensors give opportunity to analyze working space by several spots with common dataset. The use of modern automation systems and

technologies in navigation allows us to introduce new approaches in solving these tasks.

2 Formulation of problem

Improving the efficiency and functionality of small transport units for production and service includes a wide range of tasks such as transport logistics optimization, autonomous navigation and path planning, stability of the motion characteristics in a loaded / unloaded state, safety of transport and service operations, distribution of computational power among control units etc. The workspace is generally characterized by growing the intensity of traffic flows with a large number of situations which require rapid response. Finding a solution is usually a compromise between the complexity and reliability of the system and the ability to real-time reconfigure the base route in the workspace.

3 Literature review

Under the conditions of small-volume flexible production, small autonomous transport systems are in the wide demand. They give the possibility of monitoring or transporting small parts in trays or carriages in limited workspace. The popular techniques for navigation use magnetic and colored tapes, light reflective tapes with laser scanning, radio spots, computer vision system and systems with inertial adjustment of motion. Some important works in this field devoted to use special techniques of autonomous navigation.

The paper [3] describes the use of magnetic and color bands, light reflecting bands with laser scanning, radio

* Corresponding author: martin.bogdanovskiy@gmail.com

beams, systems of vision and inertial motion control for the construction of navigation systems. However, the problem of recognizing objects that may intersect a route (according to the trajectory of the object) is not resolved.

In the paper [4], the authors propose a combination of an ultrasonic sensor with a computer vision system to accurately determine distances to the frontal obstacle. However, the proposed system is used for free route planning and is very complex in data preparation for recognition in advance.

In papers [5, 6], the authors propose free-motion systems based on lidar, capable of recognizing the surrounding environment for maneuvering. However, the sensors proposed in the papers provide limited detail for interacting with objects using color techniques.

The works [7, 8] are devoted to autonomous navigation along a fixed route, constructed using proportional-integral-differential (PID) and neuro-fuzzy control laws, mainly based on deterministic and / or simulated data sensors. However, the works do not pay attention to the fact that in the case of computer vision, a sufficiently complex filtering and algorithmic adaptation to the workspace is required.

Articles [9, 10, 11] describe modern sensors for measuring acceleration and distance to objects. However, they do not indicate the feasibility of using them in the design of autonomous mobile platforms. The possibility of replacing them with artificial marking systems has not been indicated.

Using the computer vision system gives good opportunity to estimate a lot of workspace parameters for navigation. However, the sensor work is affected by a variety of environmental conditions, on which the result of recognition depends. One of the main recognition problems is the uniformity of illumination and the presence of glare surfaces. Even in the conditions of artificial lighting, brightness level changes as a result of the appearance and disappearance of objects with different light reflecting and light absorbing properties. Additional artificial marking of routes like colored leading lines and markers can also simplify or improve the navigation task, but the problem of objects recognition which cross or can cross the route (according to trajectory of object movement) is still present. So, the ability to recognize objects and obstacles in workspace variably to each situation is an intellectual task.

The use of powerful embedded computers and flexible software tools gives an opportunity to solve complex data processing tasks on small autonomous mobile platforms.

4 Proposed work

The aim of this study is to implement an autonomous navigation system based on computer vision and ultrasonic sensor that are placed on a small four-wheel drive (4WD) platform as a prototype of AGV. The tasks considered in this paper include electric circuit design and control implementation taking into account raw data filtering along the path. Solving them will let proposed small 4WD platform autonomously navigate along a defined route with the future ability to detect the

obstacles. In our study we define the following assumptions: 1. the workspace is a closed facility area; 2. navigation task includes preliminary determined location, geometric parameters of technological equipment and the artificial lighting scheme of the workspace.

4.1 Hardware implementation

All sensors are installed directly on the 4WD platform to ensure high mobility and reliability of autonomous navigation within the closed workspace. The main navigation task is to provide unhindered movement in the forward direction. For leading lines and objects detection, the computer vision system includes 1080p high resolution monocular CMOS camera with a 160° viewing angle and a variable focal length based on the chip OV5647. The data from 3-axis accelerometer and gyroscope of the MPU-6050 module are used to get a stabilized video stream and to hold the camera in a horizontal position. To avoid collisions in unpredictable situations such as incorrect objects recognition of the workspace, the wheeled platform has an additional ultrasonic distance sensor HC-SR04, which has no “blind zones” in the front plane with a measuring range from 0 to 150 cm and with an accuracy of 0.3 cm.

Estimation of the workspace, due to the dynamic characteristics of the wheeled platform and surrounding objects, requires the rapid processing of video data received from the camera. A single-board computer Raspberry Pi 3 provides enough computational power for processing video stream and to control engines and servos. Raspberry Pi 3 implements standard interfaces for wire and wireless communication for remote control, and also supports high-level programming languages. To provide maneuverability, the mobile platform uses a classic steering system. Taking into account small dimensions and model weight, a small SG90 servo actuators are used for steering the platform, providing a sufficient starting torque of 2 g/cm. To achieve required dynamical characteristics of the platform authors used DC motor HRK-370SH, which provides a torque of 79.6 g/cm at a starting current up to 28 A. As a driver we selected VN2SP30 which generates power signals to the drive system. Alignment of sensors and elements of the control system is made with taking into account the minimum length of wires connections and the usability to work with charging and programming interfaces. Creating a control system prototype for further scaling to a physical AGV needs to take into account the type of wheelbase of the real system. Therefore, wheelbase was chosen from ready-made solution, which provides similar adhesion to the surface and the area for the placement of the control, actuators, sensors and auxiliary elements. An independent cushioned suspension gives ability to reduce the vibrations that affect camera and MPU to the acceptable level. The rigid frame, was designed in KOMPAS-3D and SolidWorks and finally PLA printed, has good weight balance thanks to effective arrangement of the functional elements and battery pack. The communication and structural possibilities to plug in and fast modification of sensors, power and control units in 4WD platform design

was taking into account as well.

The final design of the assembled control unit is shown on Figure 1.

Fig. 1. The general view of control unit with the placed components.

The electrical circuit uses TWI to connect Arduino Nano and MPU-6050 to Raspberry Pi 3. Driver VN2SP30 connection to Arduino Nano uses standard PWM driver control. Arduino Nano gets power supply through the USB port.

The electrical scheme of connecting the control unit to the drive mechanisms of the wheelbase and sensors is shown on Figure 2.

Fig. 2. The electrical scheme of control units and peripheries connections.

The scheme has following items: Raspberry Pi 3 single-board computer (1); Arduino Nano to control driver and ultrasonic sensor (2); VN2SP30 driver for the main engine (3); HC-SR04 ultrasonic sensor (4); Raspberry Pi OV5647 camera (5); MPU-6050 module with 3-axis accelerometer and gyroscope (6); SG90 servomotor of the steering axle (7); HRK-370SH electric motor of the main movement (8); Raspberry Pi 3 power button (9); HRK-370SH power supply button for the electric motor (10); battery 5 V, 8800 mAh for power supply of electronic circuits (11); Battery 7.2 V, 1500 mAh for main power supply (12).

4.2 Control implementation

For safe motion stop of the 4WD platform, the control

system implements the braking mode by calculating of the speed variation which is inversely proportional to the residual distance to the obstacles. The proportional (P) control implements the rigid gear of a controlled value through feedback over distance, determined by the following equation:

$$\mu = K_p \cdot \Delta U_s, \quad (1)$$

where μ – is the influence of the regulator on the end-effector (EF) by actuator; ΔU_s – is the error signal from the comparison element (CE).

The transfer coefficient K_p is numerically equal to EF offset when the output value is changed to the unit of measurement. To calculate the P-gain for 8-bit PWM, the control signal range varies from 0 to 255. To overcome the dead zone determined by the forces of dry friction in the wheelbase and transmission, the range of PWM control signals is experimentally defined and narrowed to an interval of 130 to 255.

After the physical experiment, safety zone that guarantees obstacles avoiding by taking into account the massive inertia characteristics of the current platform was determined at the distance of 150 cm. The braking system is calibrated to this level as a reference point to start braking process. Parameter estimation of braking process that is given to the driver is shown below:

1. To set the braking system reference point we subtract the current distance to the obstacle archived by the ultrasonic sensor from safely distance:

$$D_{dist} = 150 - D_{deadzone}, \quad (2)$$

where D_{dist} – the measured distance to the obstacle in the sensor measurement system; $D_{deadzone}$ – sensitivity sensor threshold corrected to the safety shift of platform.

2. The driver PWM parameter calculated as:

$$P_{pwm} = 255 - (255 \cdot (D_{dist}/150)), \quad (3)$$

where P_{pwm} – is the calculated value of the PWM parameter for main actuator power control.

The need to simplify the information contained in the video stream from the high-resolution camera requires filtering. The Open Computer Vision Library (OpenCV) has an application level program interface (API), compatible with high-level programming language and provides interoperability for the implementation of computer vision system [13]. The camera's maximum resolution is 2592×1944 pixels. For 2 lines navigation task with stripes wider than 5 cm, the experimentally estimated low threshold of image area is 800×600 pixels to operate. Image processing and filtering takes place at several stages [14, 15]. The recognition technique begins from preliminary processing for better markers color detection and vectorization of the input image for mathematical calculations. The camera calibration needs manual tuning at the beginning in order to be able to take into account non-uniform light and color temperature. The color transformation converts blue-green-red color scheme (BGR) to hue-saturation values (HSV) to create the appropriate binary mask for target color of leading lines. Implementation of the Hough transformation [15]

helps to combine the lines to polygons formation.

The next step is to reconstruct the conditions of real workspace to analyze the efficiency of library techniques and navigation parameters. The non-uniform light leads to deviation of contrast of the images, there are false lines for the matching of floor plates. The glare of light prevents interference in leading lines detection, the marking lines have a wavy shape and a heterogeneous structure. After the initial processing and filtering of the source video, the procedure generates an array of coordinate pairs of two points (x_1, y_1, x_2, y_2) of the recognized polygonal segments of lines. To determine the actual lines, there is a pixel analysis of the fragments of the polygon lines. Each leading line is split to pixels by searching the line neighboring points coordinates. Using Python language [14], the pixel to line normalization is performed using eachPixelOfLine function. The pixel cropping function of the line is implemented with the use of the yield generator. This function provides more efficient use of memory through the processing of one line in one pass and increases the productivity of the analysis. After obtaining the points coordinates, the nearest points to the center of the lines can be found by using the get TheNearestLine function. The points coordinate values in the processing are not constant and Kalman filter [12, 14] helps to average them.

To navigate the 4WD platform, we need to find a horizontal center between the lines, which will be the reference for the adopted steering control. The center estimation is based on the following equation:

$$P_C = (P_L - P_R / 2) + P_L, \quad (4)$$

where P_C – the calculated horizontal center between the recognized lines; P_L – the nearest left point; P_R – the nearest right point.

The information about difference between the horizontal center between lines and physical camera orientation relative to the wheels helps to orient the platform on the track, using the PID-control to steer.

The general algorithm of the 4WD platform control system is shown on Figure 3.

After initializing Raspberry PI 3 and Arduino (downloading the created program, importing libraries, defining global variables) the boards verify access to the video stream. Each frame in iteration cycle is undergoing preprocessing. The image is transformed into colorless format for a more efficient procedure of locating leading lines and using openCV library. To achieve the reference point for steering axis the procedure detects center point of tracking path. After implementation of procedures for finding the closest lines the Kalman filter helps to average the central points coordinates. On the next step executes gathering of the actual data for steering, the program checks access Arduino Nano serial interface and transmits the data. During data transition, the terminal activates Arduino Nano that controls driver and ultrasonic sensor connections. To work with peripherals the board initiates the base configuration, variables and libraries. The program calculates the wheel angle and applies it to the driver of steering servomotor. An emergency brake system based on an ultrasonic sensor is triggered if the

distance to the obstacle is less than 30 cm. In this case, the 4WD platform does not move until the obstacle is present. If the distance to the obstacle is in the range of 30 to 150 cm, the speed of the wheeled platform varies in proportion to this distance by P-control.

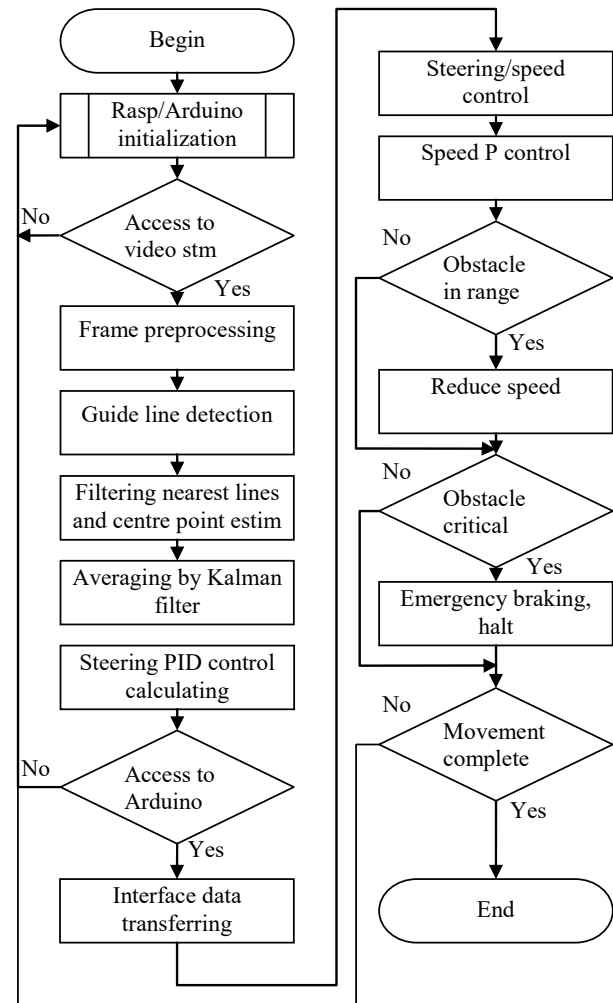

Fig. 3. The general algorithm of the 4WD platform control system.

The 4WD platform navigation software was developed using ST programming language Python3 (for Raspberry PI) and C (for Arduino Nano). Software for Raspberry Pi was developed in JetBrains PyCharm IDE [14]. Searching the artificial leading lines is procedural, with a call to external events. Arduino IDE environment uses procedure submissions with objects' environment model and abstract variables to work with system control like direction, speed, steering angle and brake.

5 Experiment

The experimental part of the study is to conduct a natural experiment, which involves the distance movement of 4WD platform along a straight path. Moreover, the nature of surface illumination and the surface itself are complex in terms of reflective properties. The recognition technique involves the use of a pair of green navigation lines, the distance between which is greater than the width

of the wheelbase.

The distance between green and white crosses determines the difference in camera and wheel orientation that must be compensated on the course. The program timer helps to synchronize the main program loop with Arduino response time. To obtain the position of 4WD platform on the path, MPU-6050 accelerometer module is used to get acceleration data in X-Y horizontal plan by the following methods [9-11].

The experimental results of processing the input stream of workspace are shown on Figure 4 and Figure 5.

Fig. 4. The platform shifts to the left.

Fig. 5. The platform shifts to the right.

The source datasheet contains discreet time and acceleration along X and Y axes. After double integration it is possible to calculate velocity and relative position of wheeled platform. The result of steering control towards linear path, obtained with MPU-6050 accelerometer module for X-Y plan, is shown on Figure 6.

Reflected light near the starting position distorts the right guide line and steering control shifts to the right. At this case, the maximum deviation along the X axis reaches 12 cm (4WD platform does not cross the track border). Measured with the accelerometer relative distance is 107 cm which is close to planned 100 cm taking into account instrumental and computational errors.

6 Discussion of research results

The AGV recognition system, built on a computer vision, gives more flexible approach to planning and maneuvering. The reliability of its use depends on the possibility of an error-free evaluation of the working area and consideration of possible situations in the control algorithms. Using a computer vision system allows to evaluate a large number of workspace options for navigation.

The operation of vision sensor is influenced by the various environmental conditions on which the result of recognition depends. One of the main problems of recognition is the uniformity of illumination and the

presence of reflecting surfaces. Even in artificial lighting conditions, the brightness level changes as a result of the appearance and disappearance of objects with different reflecting and light-absorbing properties. Extra artificial route marking, such as colored guide lines and markers, greatly simplifies the navigation task, as described in the study. The proposed approach, calculations and experimental studies of small 4WD platform show the possibility of fast navigation along the guide lines.

The limitations inherent in this study are the reflection of light leads to a mistake in steering the platform. However, as shown by the results of experimental part, the system still remains robust along the marked path, and the response of the control system is less than 0.2 seconds.

The prospect of further research is the realization of the maneuvering task around obstacles of complex geometry using object tracking by a camera with stabilization on the road using an accelerometer, as well as servicing many routes with visual marking.

7 Conclusion

1. The proposed 4WD platform provides autonomous movement and maneuvering using the steering system on a flat surface. The maximum radius of front wheels steering was 9 cm at a maximum speed of 0.8 m/s, which characterizes the high dynamics and maneuverability of navigating using guide lines.
2. The hybrid control system implements a terminal safety connection between the Raspberry PI and the Arduino Nano, allows extreme braking beyond the main control based on computer vision.
3. Implemented mathematical models and algorithmic-software implementation are intended to simplify the processing of data in the navigation direction along the guide lines. Estimating the lines perspective rate by computer vision allows additional control the speed on the way.
4. During experimental studies of autonomous driving stability on the road, the influence of uneven illumination and glare surfaces of the guide lines was estimated.

Abstract. The structure and principle of information and measurement system performance of weapon stabilization are described. Established, that the classical stabilization system consists of a stabilizing platform of the sensitive element (or block of sensitive elements), defining the absolute angle of platform α rotation, the sensing element output signal amplifier, engines and tachometers. The classical system of indirect stabilization is reviewed, its mathematical description is made. A new precision sensitive element for the information and measurement system of weapon stabilization is suggested, the principle of its performance is introduced. Constructive methods of measurement accuracy improvement in the new sensitive element are analyzed. A simulation of the new sensitive element performance influenced by the external disturbances is carried out.

1 Introduction

The Sustainable Development Strategy "Ukraine 2030" defines the purpose, vectors of movement, roadmap, priority and indicators of adequate defense, socio-economic, organizational, political and legal conditions of formation and development of Ukraine. The main purpose of the reform of the national security and defense is to improve the defense of the state, reforming the Armed Forces of Ukraine and other military formations of Ukraine in accordance with modern requirements and the experience gained during the counterterrorist operation and development of defense industry to maximize meet the needs of the army. The Armed Forces of Ukraine, priority should be given full renovation of structures, ranging from governments and ending with the staff list and units, as well as optimization of systems and standards support, the introduction of new models of weapons and military equipment, revision of tactics and strategies to meet the requirements of today.

One of the trends in the development of modern combat vehicles fire control systems is the development of a more effective weapon stabilizer with high precision parameters contributing to the increase of the military combat vehicle power and the survivability of the "crew-machine" system. In this regard, the analysis of the development of modern weapons stabilizers is an urgent task.

Relating to this, the analysis of the contemporary weapon stabilizers development is a relevant issue. Technically, the stabilizer is a set of sensors and a computing complex connected to the gun drive. Based on

the sensor performance, the parameters of the platform displacement are determined and the gun actuator is provided with control commands compensating the deviation.

In the article, an automatic control system is considered as a system of stabilization ensuring the maintenance of certain angular tower orientation in relation to the coordinate system the axes of which in a certain way are oriented in space. This coordinate system is a reference one. Depending on the specific task, this may be, for example, an inertial coordinate system or a system the axes of which are directed vertically to the moving object.

2 Literature review

Today, the development of new information and measurement weapon stabilization complexes of its sensitive elements is performed by scientists of National Technical University of Ukraine "Igor Sikorsky Kyiv Polytechnic Institute", Zhytomyr Polytechnic State University in cooperation with the public joint-stock company "Scientific and Production Association "Kyiv Automation Plant" [1].

Therefore, the relevant scientific and technical issue today is to improve the accuracy of the weapon stabilization complex.

In [2], an analysis of the current armored vehicles condition in Ukraine is performed. The effectiveness of new weapon stabilization complexes development is explained.

In [3] the structure of the pointing and armor

* Corresponding author: andru.tkachuk@ukr.net

stabilization system of light armored vehicles with a neural network controller is described. However, the point of using a neural network approach to compensate the instrumental errors has not been considered.

In [4-5], it is proposed to use a coriolis vibrating gyroscope as a sensitive element of the stabilization system. The make-up and principle of the well-known navigation complex strike- and vibroprotection of the light armored vehicles system performance is analyzed. However, there are no suggestions to improve the system technical characteristics, mathematical model and errors of the system sensitive elements analysis.

In [6], schematic models were constructed and piezoelectric transducers with additional electrical oscillating circuits to be used as a sensitive element of a weapon stabilizer were simulated. The use of models like that allows the use of applications to evaluate the characteristics and prediction of piezoelectric converters parameters and performance modes. However, the results obtained cannot be used as evidence that a sensor of such a design is more accurate than its counterparts, since no two-channel measurement error compensation schemes are considered.

Article [7] describes the use of MEMS technologies to develop sensitive elements for measuring acceleration and vibration.

The purpose is to develop a new precision sensitive element of the information and measurement system of the weapon stabilization parameters.

3 The structure of information and measurement system of weapon stabilization

The oscillations of the mobile military equipment hull are random and never stop during its movement. The amplitudes of the angular oscillations have quite high frequencies. This leads to significant movement of the target mark relative to the target and does not allow the gun pointer to hold it even with the most advanced actuators.

The oscillations in the longitudinal plane changing the angle of the gun elevation, and angular oscillations in the horizontal plane, changing the angle of horizontal guidance, have the greatest influence on the firing accuracy. They lead to considerable dispersion of shells and bullets.

Transverse angular oscillations causing the gun to tilt have less impact, but grow with the firing distance.

First and foremost, these factors cause the raise in pointing errors, increasing by 10–30 times when firing from the move compared to the stationary fire.

The classical stabilization system consists of a stabilizing platform of the sensitive element (or block of sensitive elements), defining the absolute angle of platform α rotation, the sensing element output signal amplifier, engines and tachometers.

The block diagram of the classical indirect stabilization system is presented in [8-9] and is shown in Fig. 1, where SE is a sensitive element; A – amplifier; E – engine; R – reducer; P is a stable platform; $W_1(p)$ and

$W_2(p)$ are the transfer functions of the amplifier units together with the correction means; $X(p)$ is the transfer function of the signal chain by the angle derivatives of the platform rotation α_2 with respect to the oscillating object $\lim_{p \rightarrow 0} X = 0$; $K(p)$ is the transfer function of the signal chain by the oscillation angle derivatives θ , $\lim_{p \rightarrow 0} K = 0$.

Fig. 1. Block diagram of the weapon indirect stabilization.

In [1] an example of a stabilization system that is recommended to be used as a part of aviation gravimetric systems is highlighted. In this system, the horizontal stabilized platform (GSP) has two linear accelerometers and actuators represented by special engines.

The stabilization system functions in the following way: the output signals of the linear accelerometers f_y, f_x installed on a GSP oriented in a geographical coordinate system, the sensitivity axes, respectively forwarded to north and east, will have the form [8]:

$$f_x = -(2\dot{r}\dot{\phi}_c + r\ddot{\phi}_c) \cos \chi + (\ddot{r} - r\dot{\phi}_c^2) \sin \chi - 2r\omega_E \dot{\lambda} \cos \phi_c \sin \phi - r\dot{\lambda} \cos \phi_c \sin \phi + Qg; \quad (1)$$

$$f_y = 2r\dot{\phi}_c \omega_E \sin \phi_c + 2r\dot{\phi}_c \dot{\lambda} \sin \phi_c - 2\dot{r}\dot{\lambda} \cos \phi_c - r\dot{\lambda} \cos \phi_c - 2\dot{r}\omega_E \cos \phi_c - vg, \quad (2)$$

where Q, v are the angles between the normals to the ellipsoid and geoid respectively in the meridional cross section and in the cross-sectional plane perpendicular to the meridian plane;

ϕ, ϕ_c – respective geographical and geocentric latitude;

χ – deviation from the vertical;

λ is the longitude;

g is the acceleration;

r is the radius of the location;

ω_E is the Earth rotation speed.

The received signals are directed to the onboard computer where the control signal is emerging, then coming to the engines that further adjust the GSP to zero.

If the GSP is set exactly in the vertical position, the horizontal components of the gravity acceleration are equal to zero. Considering that $Q_g = -vg = 0$, the components the onboard computer will compensate are the following:

$$f_x \Rightarrow 0 = 2r\omega_E \dot{\lambda} \cos \phi_c \sin \phi - r\dot{\lambda} \cos \phi_c \sin \phi; \quad (3)$$

$$f_y \Rightarrow 0 = 2r\dot{\phi}_c \omega_E \sin \phi_c + 2r\dot{\phi}_c \dot{\lambda} \sin \phi_c - 2\dot{r}\dot{\lambda} \cos \phi_c - 2\dot{r}\omega_E \cos \phi_c. \quad (4)$$

Neglecting the components of the second order and taking the deviation from the vertical equal to zero, there we have:

$$f_x = -r\ddot{\phi}_c; \quad (5)$$

$$f_y = -2r\ddot{\lambda} \cos \phi_c. \quad (6)$$

If case each of the signals f_y and f_x is multiplied by r^{-1} , integrated and multiplied by (-1) , then at the output of the corresponding channels we get $\dot{\phi}$ and $\dot{\lambda} \cos \phi$. The signal $\dot{\phi}$ will be used to control the GSP with respect to the x axis facing north, and the signal $\dot{\lambda} \cos \phi$ – to control the y axis facing east.

In [10] both new high-precision piezoelectric and capacitive, string, gyroscopic sensitive elements are described. They can be used as parts of a stabilization system having their advantages and disadvantages. The use of the dual-channel method to eliminate the effect of instrumental errors on the accuracy of the conversion device is described.

Nowadays, the investigation of piezoelectric sensitive elements accuracy improvement is advanced. The new precision piezoelectric sensing element being more accurate than the already existing has been developed by the article authors.

3.1 Signal conversion in piezoelectric sensing element

The analysis of the signal conversion structural diagram in the piezoelectric element is suggested:

Fig. 2. Block diagram of direct signal conversion in piezoelectric sensing element.

Block W_1 corresponds to the conversion of acceleration g , acting on PE, into mechanical stress σ . This mechanical stress is numerically equal to the force G , per unit cross-sectional area of PE. If the mechanical stress is constant over the entire cross-sectional area $PE S$, then $\sigma = G/S$, therefore [11] (Fig. 2):

$$W_1 = \frac{\sigma}{G} = \frac{G}{S} \cdot \frac{1}{G} = \frac{1}{S}. \quad (7)$$

Block W_2 corresponds to the conversion of mechanical stress σ into charge q on PE electrodes:

$$W_2 = \frac{q}{\sigma} = \frac{d_{ij} \cdot \sigma \cdot S}{\sigma} = d_{ij} S \quad (8)$$

where d_{ij} – piezomodule.

Block W_3 corresponds to the conversion of charge q into the voltage of U_{PE} at PE electrodes. The transformation of this type is reflected in Fig. 3. diagram.

In accordance with the current I scheme in Fig. 3 there can be written:

$$I = \frac{dq}{dt} = \frac{U_{PE}}{R_{PE}} + C_{PE} \frac{dU_{PE}}{dt}. \quad (9)$$

If we accept zero initial conditions, then the solution

of the differential equation will be the following:

$$U_{PE} = \frac{q}{\left(1 + \frac{1}{j\omega R_{PE} C_{PE}}\right) C_{PE}}. \quad (10)$$

Fig. 3. Equivalent W_3 link conversion scheme.

Hence the transfer function will be:

$$W_3 = \frac{U_{PE}}{q} = \frac{q}{q \cdot \left(1 + \frac{1}{j\omega R_{PE} C_{PE}}\right) C_{PE}} = \frac{1}{\left(1 + \frac{1}{j\omega R_{PE} C_{PE}}\right) C_{PE}}. \quad (11)$$

However, given the large value of R_{PE} , it is possible to accept:

$$W_3 = \frac{1}{C_{PE}} \quad (12)$$

Block W_4 describes the process taking place when the voltage on PE (transfer U_{PE} in the circle U_{ipt}). Its transfer function corresponds to the transfer function of the modifying differential link, where R_{BX} – input voltage amplifier resistance. Given the high PE resistance, the input of the amplifier is represented only by the resistance R_{ipt} .

$$U_{ipt} = (I_1 + I_2) \cdot R_{ipt}, \quad (13)$$

$$I_1 = C_{PE} \frac{dU_{CPE}}{dt}, \quad (14)$$

$$I_2 = \frac{U_{CPE}}{R_{PE}}. \quad (15)$$

In the result of substitution (14-15) in (13) we obtain:

$$U_{ipt} = \left(C_{PE} \frac{dU_{CPE}}{dt} + \frac{U_{CPE}}{R_{PE}} \right) R_{ipt}. \quad (16)$$

According to Kirchhoff's law:

$$U_{CPE} = I_2 R_{PE} = U_{PE} - U_{ipt}. \quad (17)$$

Substituting (17) into (16) obtain:

$$U_{ipt} = C_{PE} R_{ipt} \frac{d(U_{PE} - U_{ipt})}{dt} + \frac{R_{ipt}}{R_{PE}} (U_{PE} - U_{ipt}). \quad (18)$$

For further calculations we introduce the coefficient:

$$\varepsilon_R = \frac{R_{PE} + R_{ipt}}{R_{ipt}} \quad (19)$$

Divide expression (18) by the coefficient ε_R :

$$\begin{aligned} \frac{U_{ipt}}{\varepsilon_R} = & \frac{C_{PE}R_{ipt}}{\varepsilon_R} \cdot \frac{dU_{PE}}{dt} - \frac{C_{PE}R_{ipt}}{\varepsilon_R} \cdot \frac{dU_{ipt}}{dt} + \\ & + \frac{1}{\varepsilon_R} \frac{R_{ipt}}{R_{PE}} U_{PE} - \frac{1}{\varepsilon_R} \frac{R_{ipt}}{R_{PE}} U_{ipt}. \end{aligned} \quad (20)$$

Group the members of equation (20) and get rid of the denominator R_{PE} :

$$\begin{aligned} \frac{R_{PE}U_{ipt}}{\varepsilon_R} + \frac{R_{ipt}}{\varepsilon_R} U_{ipt} + \frac{C_{PE}R_{ipt}R_{PE}}{\varepsilon_R} \cdot \frac{dU_{ipt}}{dt} = \\ = \frac{C_{PE}R_{ipt}R_{PE}}{\varepsilon_R} \cdot \frac{dU_{PE}}{dt} + \frac{R_{ipt}}{\varepsilon_R} U_{PE}, \end{aligned} \quad (21)$$

$$U_{ipt} + \frac{C_{PE}R_{PE}}{\varepsilon_R} \cdot \frac{dU_{ipt}}{dt} = \frac{1}{\varepsilon_R} (C_{PE}R_{PE} \cdot \frac{dU_{PE}}{dt} + U_{PE}). \quad (22)$$

Denote the time constant $\tau = R_{PE}C_{PE}$. In the result of the time constant by equation substitution (22) and the Laplace operator introduction, we obtain:

$$(1 + \frac{\tau}{\varepsilon_R} p) U_{ipt} = \frac{1}{\varepsilon_R} (1 + \tau p) U_{PE}. \quad (23)$$

The W_4 transfer function will be:

$$W_4(p) = \frac{U_{ipt}}{U_{PE}} = \frac{1}{\varepsilon_R} \frac{1 + \tau p}{1 + \frac{\tau}{\varepsilon_R} p}. \quad (24)$$

The W_5 corresponds to the voltage amplifier transmission characteristic [11], behaving as a first order inertial link:

$$W_5(p) = \frac{K_{VA}}{1 + p\tau_{VA}}, \quad (25)$$

where K_{VA} – coefficient of the operational amplifier gain; τ_{VA} – time constant.

However, given the operation of the converter mainly in the narrow frequency range, the transmission characteristic can only be equated to the gain:

$$W_5 = K_{VA}. \quad (26)$$

Therefore, the transfer function of the signal in PE will be:

$$\begin{aligned} W(p) = W_1 W_2 W_3(p) W_4(p) W_5 = \\ = d_{ij} \cdot \frac{1}{C_{PE}} \cdot \frac{1}{\varepsilon_R} \frac{1 + \tau p}{1 + \frac{\tau}{\varepsilon_R} p} \cdot K_{AV}. \end{aligned}$$

However, PE has a tendency to discharge, so a negative feedback loop must be added to the direct signal conversion scheme.

3.2 Three-coordinate piezoelectric sensitive element

Increasing the measurement accuracy of the new precision sensitive element of the stabilization system is ensured by the fact that for each of the measurement axis Oz , Ox and Oy on the GSP a sensitive element is installed. The sensitive element is made of two channels, each of which has one piezoelectric element being identical. The

inertial masses are attached to the piezoelements piezo-plates bottom of one channel and to the top of the piezoelements piezo-plates of the second channel. The first channel piezoelectric element of each sensitive element operates on the basis of extensional strain, and the second channel piezoelectric element is based on the compression (Fig. 4).

Fig. 4. Block diagram of the precision piezoelectric sensitive element.

The three-coordinate sensitive element operates as follows: the piezoelectric elements of both channels of the three sensitive elements Az , Ax , Ay , located along the axes Oz , Ox , and Oy , are respectively accelerated. Also, the vertical acceleration of the aircraft and instrumental errors, in the result of residual non-identity of the same piezoelectric and mass structures, as well as in the result of changes in temperature, humidity and ambient pressure, affect each of the measurement axes.

If we use the algorithm of the two-channel measurement scheme performance for the two-channel piezoelectric element Az , Ax , Ay , we will receive as the on-board computer inputs 13 three signals having double values $2g_z$, $2g_x$, $2g_y$ with no vertical plane acceleration and instrumental errors value resulting in the influence of residual non-identity of identical piezoplates structures and masses, the influence of temperature change, humidity and ambient pressure. These signals are added to and amplified in the performance amplifiers OP10, OP11, OP12 and are fed to the on-board computer 13, determining:

– full acceleration vector:

$$\vec{g} = \vec{g}_x + \vec{g}_y + \vec{g}_z; \quad (27)$$

– full acceleration module:

$$\begin{aligned} |g| = \sqrt{(2km g_x)^2 + (2km g_y)^2 + (2km g_z)^2} = \\ = 2km \sqrt{g_x^2 + g_y^2 + g_z^2}, \end{aligned} \quad (28)$$

where m is the inertial masses 7, 8, 9 in each piezoelectric element;

k – piezoelectric constant being the same for all piezoelectric elements because of their identity.

The onboard computer takes control of the required calculations resulting in sending a control signal to the GSP engines. Also, the onboard computer output will get the full vector value and the full acceleration module, having no instrumental errors effect in the result of the

residual non-identity influence of the same piezoelectric and mass structures, the influence of temperature changes, humidity and ambient pressure.

3.3 Using dual-channel method

The measurement accuracy improvement is possible due to use of the dual-channel method. The method is explained by the drawing, depicting a structural diagram of a piezoelectric sensitive element (Fig. 5) [10].

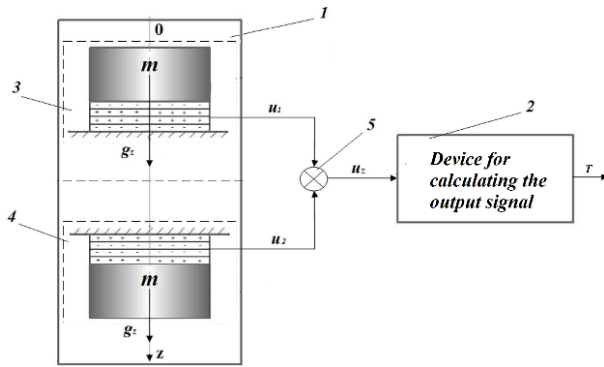

Fig. 5. Block diagram of the two-channel piezoelectric sensitive element.

The sensitive element 1 is made up of two channels, with the each one having a piezoelectric element. The piezoelectric elements of both channels are identical and are represented by piezo-plates and inertia mass, fixed on top of each other. The piezoelectric element 3 of one channel the piezo-plates of which are placed downwards, and the piezoelectric element 4 of the other channel, the piezo-plates of which are located upwards. The piezo-plates outputs of both channels are connected to the inputs of the adder 5, the output of which is connected to the input of the output signal calculation device 2.

The piezoelectric elements of both channels are affected by acceleration g , vertical acceleration $\Delta \ddot{z}$ and instrumental errors Δi resulted in the effects of residual non-identity of the same piezoelectric and mass structures, the influence of temperature changes, humidity and ambient pressure. If all these effects are exposed on the Oz axis of the new sensitive element considering that the piezoelement 3 of one channel compresses and the piezoelement 4 of the other channel stretches, we obtain [1]:

$$u_1 = k(mg + m\Delta \ddot{z} + \Delta i), u_2 = k(mg - m\Delta \ddot{z} - \Delta i),$$

where u_1 – the output electric signal of one piezoelement channel; u_2 is the output electric signal of the other piezoelement channel; m is the inertia mass weight in each of the channel; k is the piezoelectric constant.

The output electric signals u_1 and u_2 of both piezo-plates channels are summed up in the adder 5:

$$u_{\Sigma} = u_1 + u_2 = 2kmg \quad (29)$$

where u_{Σ} is output adder 5 signal.

The output adder 5 signal is fed to the output calculating device where it is calculated over a certain

period of time. In the result, we obtain the output signal of the output signal calculation device of the sensitive element, containing the double valid signal. It completely has no such measurement errors caused by the effects of vertical acceleration and instrumental errors.

4 Simulation of the operation of the sensing element

In [10], a mathematical model of a three-coordinate sensitive element of the weapon stabilization information-measuring system is presented. Software for its performance modeling under the influence of external perturbations is developed (Fig. 6).

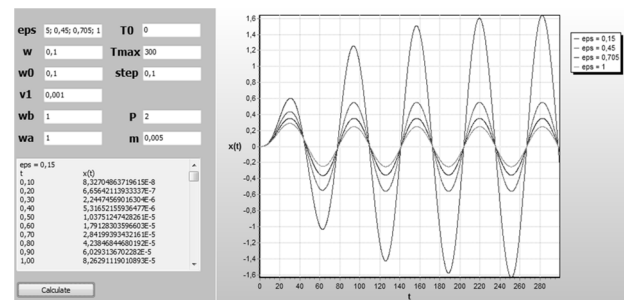

Fig. 6. Interface of the program for developing the sensitive element performance under the influence of the external perturbations.

Graphs of the PG output signal change for different perturbation frequency ω , the damping coefficient ξ and the amplitudes of vibrational acceleration perturbation are obtained. In the result of the performed digital simulation analysis, it is established that (Fig. 7-8):

- when the disturbance frequency is equal to the natural frequency of the sensitive element, the main resonance happens disappearing at $\xi = 0.705$;
- at perturbation frequencies less than the natural frequency of the sensitive element, the output signal is not distorted (subharmonic oscillations are established);
- at perturbation frequencies higher than the natural frequency of the sensitive element and $\xi \leq 0.45$ the output signal is distorted (runout happens), that is why it is to the point to increase ξ .

5 Conclusions

The analysis of the structure and performance principle of the information and measurement system of weapon stabilization, which can be installed on light armored vehicles, is made. The simplest system of indirect stabilization is reviewed; its mathematical description is made. The new precision sensitive element for the information and measurement system of weapon stabilization is suggested. The performance principle of it is introduced. Constructive methods for the new sensitive element measurement accuracy improvement are analyzed. A simulation of the new sensitive element performance under the influence of external perturbations is carried out.

Fig. 7. A typical graph of the amplitude of the output signal $x = x'(t)$, $\omega = \omega_0 = 0.1$ rad/s: 1 – $\xi = 1$; 2 – $\xi = 0.705$; 3 – $\xi = 0.45$; 4 – $\xi = 0.15$.

Fig. 8. A typical graph of the amplitude of the output signal $x = x'(t)$, $\omega = 3\omega_0 = 0.3$ rad/s: 1 – $\xi = 1$; 2 – $\xi = 0.705$; 3 – $\xi = 0.45$; 4 – $\xi = 0.15$.

Abstract. The aim of the sustainable development strategy is to introduce European standards of living in Ukraine and Ukraine’s leading position in the world. Active development is observed in information and measurement systems. The article provides a refined mathematical model of the new ballistic laser gravimeter. The composition and structure of the main errors of the ballistic laser gravimeter are given. The main errors of the ballistic laser gravimeter are calculated and estimated. The computer behavior of ballistic laser gravimeter behavior for the most unfavorable resonance modes for different ratios of disturbance values and proper ballistic laser gravimeter parameters is performed. It is suggested to use digital video as a medium of measurement information in the new ballistic laser gravimeter.

1 Introduction

Today, Ukraine needs to become a state with strong economies and advanced innovations. To do this, first of all, it is necessary to restore macroeconomic stability, to ensure sustainable economic growth in an environmentally sustainable way, to create favorable conditions for economic activity. Active development is also observed in information and measurement systems. Modern systems must meet both the technical and environmental requirements of humanity.

Measuring the absolute value of gravity acceleration with high accuracy is necessary for solving a wide range of scientific problems: determining the shape of the Earth, constructing models of motion of deep masses, predicting earthquakes, inventing deep density inhomogeneities, finding minerals, and others. Gravimeters are used to determine g . Among them, the most well-known for terrestrial measurements are ballistic laser gravimeters (BLG).

It is known that the use of computers as simulation devices can: reduce, and in some cases completely eliminate the need for physical experiments with real devices, greatly reduce the time, improve productivity, accuracy of research all this has a significant economic effect.

The article [1] describes an advanced gravimetric system for low flow rates that was developed by the National Institute of Metrology of Japan (NMIJ) to perform the method of flight-start and stop calibration. However, there is no description of the mathematical model.

The paper [2] presents the regional gravimetric survey of the central part of the Republic of Slovenia. The need for a new gravimetric survey, the survey plan and the actual field measurements are presented. Data processing, control calculations, data adjustment in the form of a gravimetric network and accuracy estimations of the results obtained during the regional gravimetric survey are described.

Today new information-measuring gravimetric systems, methods and tools of gravimetric measurements are being developed by the Ukrainian scientists of National Technical University of Ukraine “Igor Sikorsky Kyiv Polytechnic Institute”, Zhytomyr Polytechnic State University [3].

But there is no information in the literature regarding the mathematical model of BLG that is required for further computer modeling. In this regard, the analysis of the device, the study of the main errors affecting the measurement is an urgent task.

The task of measuring gravity by ballistic methods is to measure length and time. This follows, for example, from the analysis of the dimension of acceleration. Therefore, the mathematical model should reveal the analytical relation of the path traveled by the test body with time and external influences. The most constructive approach would be to build a model in which, on the one hand, the free motion of the test body in the inertial coordinate system is considered, taking into account the vertical gradient of the gravity acceleration and the forces of resistance, and on the other, the law of motion of some coupled coordinate system is shifted under the influence of external inertial influences and holds the reference system of the gravimeter.

* Corresponding author: gum_ann@ukr.net

Considering all researches, it can be concluded that the current scientific and technical problem today is to improve the accuracy of measurement of the gravity acceleration.

The purpose is to get a mathematical model of the new BLG and improve the measurement accuracy of the gravity acceleration.

2 Suggestions and solutions

Consideration of the free motion of a test body tilted vertically upwards in an inertial coordinate system is reduced to solving a nonlinear 2nd order differential equation of the following form:

$$m \cdot \ddot{z} = m \cdot (g_0 + \alpha \cdot z) - \gamma_1 \cdot \dot{z} - \gamma_2 \cdot (\dot{z})^2, \quad (1)$$

where m is the mass of the test body; z is the vertical coordinate; α is the vertical gradient; γ_1 , γ_2 are the coefficients that determine the contribution of resistance forces proportional to the first and second degrees of speed of motion of the test body.

Solving equation (1) by successive approximation using the Laplace transform and then decomposing it by z , leads to the following equation:

$$z(t) = g_0 \cdot \sum_{n=0}^{\infty} A_n \cdot t^n, \quad (2)$$

where A_n is the set of coefficients ($n = 0, 1, 2, \dots$) determined from the conditions of motion of the test body in the ballistic block relative to the reference system.

This expression describes the motion of the test body in the inertial coordinate system. The coordinates of a test body in real-world measurements of the gravity acceleration is determined by the fixed coordinate system that exposed perturbation an inertial system are uniquely dependent on its coordinates in the connected system:

$$\bar{R}_i = \bar{r} + \bar{R}, \quad (3)$$

where \bar{R}_i – a radius vector of the test body in the inertial system;

\bar{r} – a radius vector of the test body in the connected system;

\bar{R} – a radius vector that describes the offset of a connected system.

Generally, the ballistic gravity meter is operated so that the sensitivity axis (in our case the z axis) is held vertically. Therefore, equation (3) can be simplified:

$$S(t) = z(t) + R_z(t) \quad (4)$$

In this expression, the component $S(t)$ describes the behavior of the test body in the inertial system, and component $R_z(t)$ – the influence of external perturbations.

Algorithms for measurements of the gravity acceleration using the described model are very diverse, both by the method of realization of free movement of the test mass and by methods of measuring the path and time.

Depending on the method of realization of the free movement of the test body, all terrestrial methods of determining g can be divided into two groups

- with asymmetrical free movement;
- with symmetrical free movement.

Using symmetric methods (both branches of the parabola in Fig. 1), the test body is tilted up, and the path and time measurements are made on the left and right branches of the trajectory.

When using asymmetric methods (right branch of the parabola in Fig. 1), the test body moves freely (falls) in the vacuum.

Fig. 1. The flight path of the test body in ballistic gravimeter: $C_1 - C_4$ – observation levels; $t_1 - t_4$ – moments of end of measurement intervals; $S_1 - S_4$ – measurement intervals.

These methods are distinguished by the relatively simple implementation of free movement and the absence of the need to apply impulse (shock) force when starting the test body, which depends on the height of the throw, which greatly improves the dynamic conditions of gravimeter [4, 5].

The advantages of symmetric methods include the possibility of virtually complete elimination of systematic errors (which is proportional to the first degree of speed of motion of the test body) with a relatively simple measurement algorithm, as well as the possibility of reducing the vertical dimensions of the device, because at the same height of the gravimeter is the total path traveled by the body in this case it will be big. However, at the moment of throw there is a pulse reactive force, which introduces an error in the measurement results.

Now we will present the set and structure, calculate and evaluate the main errors of BLG.

A further increase in accuracy is hampered by a number of circumstances, both of a fundamental (physical) and technological (economic) nature. Therefore, there is the question of optimal accuracy, which depends on many factors and is determined by limitations. These limitations need to be known so that, on the one hand, you can use all of the precise possibilities presented by the theory, and on

the other hand, do not make unsuccessful attempts to increase accuracy beyond what is possible.

Let us analyze how practical considerations shape the conditions for the required accuracy of measurements in gravimetry.

Let us take a slow (quasi-static) process. It is necessary with the given reliability β to obtain their value $\Delta x(t)$ (Fig. 2), measuring the process $x(t)$ over time τ .

Fig. 2. The dependence of the permissible error on the drift velocity of the measurement process: $S(t)$ – change of learning parameter of process during observation τ .

The magnitude measured by $\Delta x(t)$ and the error $\delta(t)$ of BLG are related by the relation:

$$\Delta x(t) \geq \beta \cdot \delta(t), \quad (5)$$

where $\beta \geq 1$ is the number that characterizes the reliability of the measurement.

Then the Lagrange theorem on the mean in the interval under consideration can be written as follows:

$$\frac{x(t_2) - x(t_1)}{t_2 - t_1} = \frac{\Delta x(t)}{\tau} = \frac{dx}{dt} = V(t),$$

whence, taking into account equation (5), we obtain:

$$\delta(t) \leq \tau \cdot \frac{V(t)}{\beta} \quad (6)$$

From equation (6) it follows that in the case of measurements of slowly changing processes, in addition to trivial to the accuracy of the measuring instrument, the requirements are also not completely obvious (measurement triviality is contained in the fact that the error of the device $\delta(t)$ must be smaller the more reliable the result is):

1) the error value of the instrument must change over time if the process speed $V(t)$ is variable;

2) the value of the error of the instrument must be less than the smaller time interval τ spent to detect changes ΔS .

Based on equation (6), we determine the maximum permissible value of $\delta(t)$.

If $\tau = 0,1$; $\beta = 1$; $V = 1 \mu\text{Gal}$ then $\delta = \frac{0,1 \cdot 1}{1} = 0,1 \mu\text{Gal}$ or in relative terms $\delta/g_0 = 1 \cdot 10^{-10}$.

Such an error in the measurement of the gravity acceleration is currently needed to solve some geological problems [6]. Approximately the same accuracy order is

required by an exemplary gravimeter for calibration of accelerometers.

But this accuracy, at this point in time, is close to the limits recognized by some instrumental and fundamental limitations.

As is known, the error of the laser interferometer, which is a device for reproducing a unit of length, has a significant effect on the error of the gravimeter. Let us define one of the errors of the interferometer - the diffraction error caused by the limited aperture of the light beam:

$$\frac{\Delta g}{g} \approx 0,1 \cdot \left(\frac{\lambda}{d}\right)^2.$$

At wave length $\lambda = 0,633 \mu\text{m}$; beam diameter $d \approx 2 \text{ mm}$:

$$\frac{\Delta g}{g} = 0,1 \cdot \left(0,633 \cdot \frac{10^{-6}}{2} \cdot 10^{-3}\right)^2 \approx 1,0017225 \cdot 10^{-8}.$$

In modern gravimetry, the total interaction of gravitational obstacles, with the exception of the influence of the sun and the moon, is considered so small in comparison with the equilibrium of inertial forces that it can be neglected [7]. The very exclusion of the influence of inertial forces on the results of measuring the gravimeter is, at this point in time, one of the main difficulties in improving the accuracy of the determination of the gravity acceleration.

When performing gravimetric measurements of higher accuracy, a number of systematic errors are taken into account by making appropriate corrections, such as light pressure corrections, first and second order vertical and horizontal gradients, vacuum resistance, etc.

Although accurate accounting for these errors and corrections is now more difficult than measuring acceleration itself, it is fundamentally feasible. However, there are fundamental limitations that cannot be eliminated by any tools or technological means. These include the approximation of the set value of the speed of light, quantum-mechanical constraints, the limits of the accuracy of determining the acceleration gradients, fluctuations, etc.

Limitations that impose quantum mechanical laws:

$$(\Delta \bar{E})^2 \cdot (\Delta \bar{t})^2 \geq h^2 \quad (7)$$

This inequality imposes a restriction on the measurement of energy (velocity) of the body if it is to be measured at a precise time. As noted above, the acceleration g can be determined from the relation:

$$g = \frac{V - V_0}{t - t_0}.$$

Find the variance of the gravity acceleration:

$$D = M_2\{g\} = \frac{g^2}{(t - t_0)^2} \cdot [(\Delta \bar{t})^2 + (\Delta \bar{t}_0)^2] + \frac{1}{(t - t_0)^2} \cdot [(\Delta \bar{V})^2 + (\Delta \bar{V}_0)^2], \quad (8)$$

where $(\Delta \bar{t})^2$ and $(\Delta \bar{t}_0)^2$ – the variance (uncertainty) of the end and start points of time; $(\Delta \bar{V})^2$ and $(\Delta \bar{V}_0)^2$ – dispersions of the finite and initial velocities of the free-fall body.

Rewrite equation (8) using equation (7):

$$D = \frac{g^2}{(t - t_0)^2} \cdot [(\Delta \bar{t})^2 + (\Delta \bar{t}_0)^2] + \frac{h^2}{m^2(t - t_0)^2} \cdot \left[\frac{1}{V^2(\Delta \bar{t})^2} + \frac{1}{V_0^2(\Delta \bar{t}_0)^2} \right], \quad (9)$$

Investigating equation (9) for the extremum, let us determine $(\Delta \bar{t})^2$ and $(\Delta \bar{t}_0)^2$, that correspond to the minimum D

$$(\Delta \bar{t})^2 = \frac{h}{mVg} \text{ and } (\Delta \bar{t}_0)^2 = \frac{h}{mV_0g}.$$

So, we see that measuring of the gravity acceleration more accurately than 10^{-9} is impossible in principle due to quantum mechanical constraints, as well as fluctuations in length and time measures.

After further analysis of the literature, it can be seen that the error caused by the linear drift of the scale factor of the BLG is $\Delta_l = 0.002\%$.

The error value is insignificant, so it is possible to neglect such a linear drift of the scale factor.

The error from the portable (relatively BLG) angular velocity of the Earth rotation is determined by the formula:

$$\Delta_E = \frac{\omega_z}{k},$$

where k is the transmission coefficient of BLG, ω_z is the vertical component of the portable angular velocity of the Earth rotation.

Note that the vertical component of the portable angular velocity of the Earth rotation is:

$$\omega_z = \omega_E \sin \phi$$

Find the numerical value Δ_E for such parameters $k = 5 \cdot 10^{-3} \text{ kg} \cdot \text{m}$, $\omega_E = 7,29 \cdot 10^{-5} \text{ s}^{-1}$.

The maximum value of the term $\frac{\omega_E \sin \phi}{k}$ corresponding to $\phi = 90^\circ$ is $1,46 \cdot 10^{-8} \text{ rad}$. That is, the error value Δ_E is small and can also be neglected.

The possibility of increasing the accuracy and speed of a ballistic gravimeter by determining the influence of the deviation of the gravity axis of the gravimeter from the local vertical direction by using digital video has been investigated [8].

The problem is solved by the fact that in the already existing gravimetric system with high-precision alignment of the axis of gravity of the gravimeter is additionally introduced video camera 5, the processor of linear approximation of the label 6, the reflecting element 7, the photoelectric autocollimator 8, and the body of the gravimeter 1 is plotted, the direction of which coincides with the direction of the axis of gravity of the gravimeter 1, and the label is optically connected to the input of the camcorder 5, the output of which is connected to the input of the processor 6 linear approximation of the label, the output of which is connected to the first input of the digital

computer 3, the second input of which is connected to the output of the photoelectric autocollimator 8, the input of which is optically connected to the reflecting element 7, which is attached to the housing gravimeter 1 (Fig. 3).

Fig. 3. Schematic diagram of a gravimetric system with high precision alignment of the axis of sensitivity of the gravimeter.

High-precision alignment of the axis of sensitivity of the gravimeter in three-dimensional space is ensured by the high-precision exposure in the three-dimensional space of the position of the plane corresponding to the surface of the reflecting element. Moreover, the mark and the reflecting element are fixed on the body of the gravimeter so that the direction of the mark coincides with the direction of the axis of sensitivity of the gravimeter, and the surface plane of the reflecting element was parallel to that axis of sensitivity [9].

The photoelectric autocollimator and camcorder are also pre-oriented in three-dimensional space so that their optical axes are perpendicular to the local vertical direction. With the help of a photoelectric auto-collimator, the deviation of the surface plane of the reflecting element from the position when it is perpendicular to the optical axis of the auto-collimator is estimated. A signal proportional to the degree of this mismatch is fed to the computer. The computer manages the spatial position of the platform in such a way so to eliminate this mismatch.

The result is an arrangement of the axis of sensitivity of the gravimeter in a vertical plane that is perpendicular to the optical axis of the photoelectric autocollimator and in which the direction of the local vertical is located.

However, the gravity axis of the gravimeter may be located in the specified vertical plane, but deviate some angle from the direction of the local vertical. This deviation can be determined by the tag, camcorder, and linear tag approximation processor. With the help of a digital computer that manages the spatial position of the platform, this deviation can be eliminated.

The result is a highly accurate alignment of the gravity axis of the gravimeter in three-dimensional space and, accordingly, its high-precision coincidence with the direction of the local vertical and the full vector of gravity acceleration.

Thus, in the gravimetric system, the accuracy of measuring the acceleration of the force of gravity is significantly increased.

3 Simulations

The problem of investigating the influence of disturbance action parameters and some own BLG parameters on the work with the help of a computer is solved.

We use the equation of motion BLG, writing it in the form:

$$\ddot{\alpha} + \dot{\alpha}[2n - L \sin(\omega t + \varepsilon)] + \omega_0^2 \alpha = N \sin \omega t, \quad (10)$$

where $L = \frac{c_1'}{H^2} m l w_b$, $N = \frac{m l k_1}{H^2} w_a$ – vibration parameters.

Given $M(t) = 2n - L \sin(\omega t + \varepsilon)$, $D(t) = \omega_0^2$, then

$$\ddot{\alpha} + \dot{\alpha} \cdot M(t) + D(t) \cdot \alpha = 0, \quad (11)$$

where $M(t)$ and $D(t)$ are T -periodic functions, $\dot{M}(t)$ and $\dot{D}(t)$ assume integrated piecewise-continuous.

The equation of the form (11) can be reduced to a similar one without changing the characteristic indices, where $M(t) = \text{const}$.

$$\int_0^t M(t_1) dt_1 = \aleph t + M_1(t),$$

where

$$\aleph = 2n; M(t_1) = \int_0^t [M(t_1) - \aleph] dt = \frac{L}{\omega} \cos(\omega t + \varepsilon),$$

and $M_1(t)$ is T -periodic function.

Replacing

$$\alpha = e^{-\frac{1}{2}M_1(t)} x = e^{-\frac{1}{2\omega} \cos(\omega t + \varepsilon)} x, \quad (12)$$

we get

$$\ddot{x} + 2n\dot{x} + F(t)x = 0, \quad (13)$$

where

$$F(t) = D(t) - \frac{1}{4}M^2(t) - \frac{1}{2}\dot{M}(t) + \frac{1}{4}\aleph^2 = \omega_0^2 + \nu_0 \sin(\omega t + \varepsilon + \sigma_8), \quad (14)$$

where $\sigma_8 = \arctg \frac{\omega}{2n}$, $\nu_0 = \frac{L\sqrt{\omega^2 + 4n^2}}{2}$.

Given (5.1) and (5.5), expression (5.4) can be written as

$$\ddot{x} + 2n\dot{x} + [\omega_0^2 + \nu_0 \sin(\omega t + \varepsilon + \sigma_8)]x = N \sin \omega t \quad (15)$$

or, taking into account the real BLG parameters:

$$\ddot{x} + 2\xi\omega_0\dot{x} + (\omega_0^2 + \nu_1 w_b \sin \omega t)x = 0,625w_a \sin \omega t, \quad (16)$$

where $\nu_1 = \frac{\nu_0}{w_b}$.

Therefore, the BLG motion equation (10) is transformed into one equation (16), which is convenient for computer simulation. The equation obtained is a Mathieu-Hill equation [10-12].

The graphs of some functional dependences for certain values w_a, w_b, ω , as well as the values of the damping coefficient ξ , are shown in Fig. 4, 5, 6.

Fig. 4. Graphs of change of output signal for different values ω .

Fig. 5. Graphs of change of the output signal $x(t)$ for different values of the damping factor ξ .

Fig. 6. Graphs of output signal $x(t)$ changes for different values w_a, w_b .

The graphs show that:

- at perturbation frequency $\omega = \omega_0 = 2,5 \text{ s}^{-1}$ the main resonance occurs, the most dangerous for the BLG;
- at perturbation frequency $\omega = \omega_0/2 = 1,25 \text{ s}^{-1}$, $\omega = \omega_0/3 = 0,83 \text{ s}^{-1}$ the output signal is not distorted (sub harmonic oscillations are set);

– at perturbation frequencies $\omega = 2\omega_0 = 5 \text{ s}^{-1}$, $\omega = 3\omega_0 = 7,5 \text{ s}^{-1}$ the output signal is distorted (beating is set);

– increasing the amplitudes of horizontal accelerations does not affect the amplitude of the forced oscillations of the BLG $x(t)$;

– the amplitudes of the forced oscillations along the axis of the BLG sensitivity are directly proportional to the amplitudes of the perturbing vibration accelerations along the axis of the BLG sensitivity.

In order to compare the above information, the results of modeling the equations of motion of BG on the computer are summarized in Table 1.

Table 1. The amplitudes of the steady forced oscillations of the BLG.

ω, s^{-1}	α, rad
0,83	$0,22 \cdot 10^{-7}$
1,25	$0,65 \cdot 10^{-7}$
2,5	$1,86 \cdot 10^{-6}$
5,0	$0,93 \cdot 10^{-6}$
7,5	$4,7 \cdot 10^{-7}$

Comparing the amplitudes of the steady forced oscillations of the BLG at $\omega = \omega_0$, $3\omega = \omega_0$, $2\omega = \omega_0$, $\omega = 2\omega_0$, $\omega = 3\omega_0$; $\xi = 1$; $w_a = w_b = 1 \text{ m/s}^2$, calculated in accordance with expression (12) (Table 1), it is seen that the amplitudes of the steady forced oscillations of the BLG are greatest, provided that the frequency of the natural oscillations of the BLG and the disturbing influence are equal.

Digital simulation of the effect of perturbation parameters on the BLG, as well as the eigen parameters, confirmed the main advantage of the BLG over the known gravimeters – its higher accuracy (mean square error of $0,1 \mu\text{Gal}$).

4 Conclusions

A refined mathematical model of the new BLG was obtained. The composition and structure of the main errors of the BLG are given. The main errors of the BLG are calculated and estimated. The computer simulation of BLG behavior for the most unfavorable resonance modes for different ratios of disturbing factors and intrinsic BLG parameters is performed. The conclusions made in the analytical study of the work of BLG are confirmed: the most dangerous from the point of view of resonance occurrence is only the case of coincidence of perturbation frequency with the frequency of natural BLG oscillations. As the damping factor increases, the resonance disappears. The main advantage of BLG over the known gravimeters was confirmed – its greater accuracy (mean square error of $0,1 \mu\text{Gal}$). It is proposed to use digital video in the new BLG as a carrier of measurement information. This extends the functionality and also significantly improves the accuracy of measurements of the gravity acceleration. This reflects the modern engineering and technological solutions of the information technology era in the sustainable development of society.

Abstract. The article explores data mining algorithms, which based on rules and calculations, that allow us to create a model that analyzes the data provided by searching for specific patterns and trends. The purpose of this work is to analyze correlation-regression algorithms on a statistical dataset of chronic diseases. Data mining allows building many models, multiple algorithms can be used within a single solution. The article explores the algorithms of clustering, correlation analysis, Naive Bayes algorithm for obtaining different views of data. Since diabetes is one of the most dangerous chronic diseases, the pathogenesis of which is a lack of insulin in the human body, which causes metabolic disorders and pathological changes in various organs and tissues. As a result, it leads to disability of all functional systems of the body. It was decided to investigate the data related to this disease. Also, the quality of the developed methods of information retrieval from the dataset was evaluated and the most informative features were identified. The developed methods were implemented in the system of intellectual data processing. Past studies show promise of using data mining methods to improve the quality of patient care.

1 Introduction

The health care system is fully controlled by the state. According to the determined vectors and strategic vision of the Sustainable Development Strategy of Ukraine until 2030, one of the focuses is on providing an effective public health system, providing effective medical services, which is impossible without the use of modern information technologies [1]. The use of modern information technology is impossible without green IT [2].

The complexity of the experiments in this area is due to the object of the study, that is, human health. Most experiments on human health have legislative restrictions, as this can cause damage and prevent human rights. Therefore, the use of methods of data mining, in this case, for the analysis of already collected data can allow revealing a lot of hidden information, based on which further decisions can be made.

There are many algorithms for data mining. The purpose of this is to find patterns in the data. The knowledge gained through the methods of Data mining is accepted to be represented in the form of regularities (patterns) [3]. The article deals with classification algorithms and correlation-regression algorithms.

1.1 Analysis of published data

Volozhanin defines the basic concepts of correlation and calculates the correlation coefficient between the digital (numeric) value of each factor and the result of the sports.

But the author does not use mathematical tools for analysis and does not provide specific research results [4]. The article [5] by the author team researched the detection of pathogenetic correlations between the parameters of standard laboratory methods of research in patients with iron deficiency anemia with chronic blood loss. Using the language R, a statistical analysis of the laboratory parameters was performed and the inherent correlations were established. Differences were found in correlation relationships between indicators, which reflect profound pathogenetic changes, using differentiation. These results have practical value for the assessment of the severity of metabolic damage and to monitor treatment effectiveness.

The systematic approach to the training of athletes is considered in the article [6]. Usage patterns of mathematical statistics methods in sports analysis are considered. Out of several methods, more reliable ones for detecting correlation relationships were chosen. The article uses a Fechner coefficient to determine the closeness of links between objects.

The article [7] presents an approach to the recognition of localized road signs using the method of support vector machine and histograms of oriented gradients. A method of plotting histograms of oriented gradients that do not depend on image size is proposed. For problems with multiple classes, the method of support vector machine is generalized. The experimental data show the advantages of the proposed method. The disadvantage of this study is that the experiment is not sufficiently covered.

The article of Andreeva [8] investigates the correlation analysis of the results of sociological researches to the

* Corresponding author: lobanchikovnadia@gmail.com

problem of attitude of the city population to the number of days off needed to celebrate the new year was explored. Statistical relationships were found between different feature groups. This study does not describe the algorithms that were used in the work.

1.2 Formulation of the problem

The purpose of the study is to use the algorithms of data mining for the processing of statistics and research into green IT creation and implementation processes:

- researching correlation-regression algorithms;
- the use of the support vector method;
- conducting research (exploratory) analysis;
- selection of the most unexpected dependencies.

2 Description of the data source

Unfortunately, medical statistics in Ukraine are not yet able to provide the necessary amount of statistical information for analysis and boast the extensive use of green IT. Therefore, the US Centers for Disease Control and Prevention (CDC) may be one of the sources for research. Chronic Disease Statistics in 500 U.S. cities were selected for data analysis based on information collected by the CDC [9]. This data is unique in itself because it covers 103 million people aged 18 and older and has 27,210,000 records across different statistical reporting territories, with populations ranging from 50 to 26,980. Also included in the data is the state, district, city, geographic coordinates, which further expands the analysis based on other statistics, for example, average household income, unemployment rate and more.

The indicators are divided into three main groups:

1. Unhealthy lifestyle (5 indicators).
2. Chronic diseases (13 indicators).
3. Population coverage by preventive methods (9 indicators).

All metrics are presented as a percentage of the population and a range of errors. The CDC, as a government organization, has sufficient resources to ensure that statistical information is collected and further processed. Chronic illness statistics are already a normalized database and contain information from verified sources.

Naive Bayes classifier belongs to a family (type) of probabilistic classifiers using the Bayes' theory. Despite its simplicity, the Naive Bayes classifier remains one of the most popular methods of solving the problem of text categorization, the problem of identifying documents that fall into one category or another. The purpose of the naive Bayesian classifier is to calculate the conditional probability by the formula (1):

$$p(C_k|x_1, x_2, \dots, x_n) \quad (1)$$

For each of k the possible outcomes or classes C_k .

Let (may, if) $x = (x_1, x_2, \dots, x_n)$. Using Bayes' theorem, we can obtain, get the formula of the form (2):

$$p(C_k|x) = \frac{p(C_k)p(x|C_k)}{p(x)} \propto p(C_k)p(x|C_k) =$$

$$= p(C_k, x_1, x_2, \dots, x_n) \quad (2)$$

The joint probability can be written as (3):

$$\begin{aligned} p(C_k|x_1, x_2, \dots, x_n) &= \\ &= p(x_1|x_2, \dots, x_n, C_k) \cdot p(x_2, \dots, x_n, C_k) = \\ &= p(x_1|x_2, \dots, x_n, C_k) \cdot p(x_2|x_3, \dots, x_n, C_k) \cdot \\ &\cdot p(x_3, \dots, x_n, C_k) = p(x_1|x_2, \dots, x_n, C_k) \cdot \\ &\cdot p(x_2|x_3, \dots, x_n, C_k) \cdot p(x_n|C_k) \cdot C_k \end{aligned} \quad (3)$$

Assume that all functions x mutually independent, we can get the formula (4):

$$p(x_1|x_2, \dots, x_n, C_k) = p(x_1|C_k) \quad (4)$$

Therefore, the formula can be written as (5). So, it is the final formula for naive Bayesian classifiers. We offer training and testing in Python programming language.

$$\begin{aligned} p(C_k|x_1, x_2, \dots, x_n) &\propto p(C_k, x_1, x_2, \dots, x_n) = \\ &= p(x_1|C_k) \cdot p(x_2|C_k) \dots \cdot p(x_n|C_k) \cdot p(C_k) = \\ &= p(C_k) \prod_{i=1}^n p(x_i|C_k) \end{aligned} \quad (5)$$

The training model is represented in the Python programming language is:

```
def train_dataset_for_column(column_to_predict):
    column_to_predict = column_to_predict
    train, test = train_test_split
        (data_only_crude_prev, test_size=0.2)
    best_chooser = BestSelectionTrainAlgorithm(
        lambda: linear_model.LinearRegression())
    best_chooser.max_best_indicators_count = 5
    best_chooser.low_score_for_best = 0.7
    best_chooser.max_combine = 2
    best_chooser.y_column_preparer =
        lambda data_frame: data_frame.astype(int)
    best_indicators =
    best_chooser.best_indicators_from(train, test,
    column_to_predict)
    descr = 'Best indicator for ' +
        column_to_predict + '\n'
    for train_result in best_indicators:
        train_result.columns_by_predict, accuracy=2.0)
        descr = descr + '
'.join(train_result.columns_by_predict) + ' ' +
        column_to_predict + ': ' +
        str(train_result.score) + '\n'
        str(train_result.model.intercept_) + '\n'
        descr = descr + "\n\n"
    print(descr)
```

The testing model is represented in the Python programming language is:

```
def test_prediction_accuracy(model, test,
    column_to_predict, column_by_predict,
    accuracy=0.0):
    count_of_test_rows = len(test)
    count_of_close_predicted = 0
    test_by = test[column_by_predict].values
    test_to = test[column_to_predict].values
    predicted_values = model.predict(test_by)
    for i in range(0, count_of_test_rows):
        if isclose(predicted_values[i], test_to[i],
            abs_tol=accuracy/2):
            count_of_close_predicted += 1
    return count_of_close_predicted/
```

```
count_of_test_rows
if __name__ == '__main__':
    mp.freeze_support()
    columns = data_only_crude_prev.columns.values
    p = mp.Pool(3)
    results = p.map(train_dataset_for_column,
                    columns)
```

Support vector machine provides significant accuracy with less computing power and can be used for both regression and classification problems. The purpose of the algorithm is to find a hyperplane in an N -dimensional space (N is the number of features) that clearly classifies data points (see Fig. 1).

Fig. 1. Possible hyperplanes.

To separate the two classes of data points, there are many possible hyperplanes to choose from. The goal of the algorithm is to find the plane, which has a maximum margin (stock, reserve), that is, the maximum distance between data points of both classes. Maximizing the margin (stock, reserve) distance provides some reinforcement so that future data points can be classified with greater confidence.

Data points that fall on either side of the hyperplane can be classified into different classes. Also, the dimension of the hyperplane depends on the number of features (sighs, characteristics). If the number of input objects is 2, then the hyperplane is just a line. If the number of input objects is 3, then the hyperplane becomes a two-dimensional plane. It becomes difficult to imagine when the number of functions exceeds 3 [11].

The purpose of the algorithm is to maximize the difference between the data points and the hyperplane. A loss function that helps maximize margin is a hinged loss. The cost function and gradient renovation, (6):

$$c(x, y, f(x)) = \begin{cases} 0, & \text{if } y * f(x) \geq 1 \\ 1 - y * f(x), & \text{else} \end{cases} \quad (6)$$

Cost is 0 if the predicted value and the actual value have the same sign. If this condition is not fulfilled – it is necessary to calculate the amount of damage. We also add a parameter of the regularization of the cost function. The task of the regularization parameter is to balance the maximization of margins and losses. After adding the regularization parameter, the cost functions are as follows, (7):

$$\min_w \lambda ||w||^2 + \sum_{i=1}^n (1 - y_i(x_i, w))_+ \quad (7)$$

Once the loss function is known, it is possible to take private derivatives by weight to find gradients. Using gradients can be updated weight, (8), (9):

$$\frac{\delta}{\delta w_k} \lambda ||w||^2 = 2\lambda w_k \quad (8)$$

$$\frac{\delta}{\delta w_k} (1 - y_i(x_i, w))_+ = \begin{cases} 0, & \text{if } y_i(x_i, w) \geq 1 \\ -y_i x_{ik}, & \text{else} \end{cases} \quad (9)$$

When the model makes a mistake in the prediction of a data point class, it is necessary to include the loss along with the regularization parameter to update the gradient, (10):

$$\omega = \omega + a \cdot (y_i \cdot x_i - 2\lambda\omega) \quad (10)$$

When the model correctly predicts the data point class, all that is need to do is to update the gradient of the regularization parameter, (11):

$$\omega = \omega - a \cdot (2\lambda\omega) \quad (11)$$

The Best Selection Train Algorithm class was developed to implement the **support vector machine**.

For the selection of indicators that are significantly correlated with each other, this class has the following fields:

1. `max_best_indicators_count` – the maximum number of indicators to be selected.
2. `low_score_for_best` – a minimum estimate of the accuracy of the model (used to ensure that the model based on the model was considered the best).
3. `max_combine` – the number of elements in the array based on which the prediction is made (it should be noted that the long-term operation of the algorithm may be required when this indicator is of great importance).
4. `y_column_preparer` – the method used to prepare the test data (for example, the Bayesian algorithm cannot predict non-discrete values (such as float), so in this method, the Float value can be converted to Int).

The training model implements the following methods:

1. `def fit(self, X, y)` – a method for training the model, where **X** – an array of values that the training is based on, **y** is the expected value.
2. `def score(self, X, y, sample_weight=None)` – a method for estimating the quality of model prediction, where **X** – an array of values on which testing takes place, **y** is the expected value.

The model is built using the support-vector machine and depends only on the subset of the training data and in some cases gives the best result of regression analysis.

Exploratory data analysis. To investigate the relationship between the data, we use the Pearson correlation coefficient (Table 1), the values of which are interpreted based on absolute values. Possible values vary from 0 to ± 1 . To evaluate the bond strength, a Cheddock table is usually used, according to which, absolute values less than 0.3 indicate weak bond strength, 0.3 to 0.5 – moderate, 0.5 to 0.7 – significant, 0.7 – 0.9 – high, a value greater than 0.9 – very high. Figure 2 presents the matrix of correlation indicators (heat map) obtained by using linear regression and estimation of the results of the coefficient of determination (R-square).

After analyzing the indicators, some patterns have been identified that are logical. For example, a visit to a dentist leads to tooth loss. The lack of health insurance for

adults 18-64 years old (ACCESS2_CrudePrev) correlates with the prevalence of visits to a dentist or dental clinic for adults 18 years of age (DENTAL_CrudePrev). A correlation was found between such indicators as the prevalence of arthritis in adults 18 years of age (ARTHRITIS_CrudePrev) and high blood pressure in adults 18 years of age (BPHIGH_CrudePrev), a correlation coefficient of 0.75.

Fig. 2. Matrix of correlation indicators.

Correlations were also found between such indicators as the prevalence of arthritis among adults aged 18 and over (ARTHRITIS_CrudePrev) and chronic obstructive pulmonary disease in adults 18 years and older (COPD_CrudePrev) – correlation coefficient of 0.65.

Special attention has been paid to the correlation of diagnosed diabetes mellitus in adults aged 18 years (DIABETES) with other diseases. Diabetes mellitus is a disease that is included in the group of “leaders” along with cardiovascular and oncological diseases and is called the “disease of the century”. If it was previously thought that diabetes is a disease of the elderly, then in the 21st century, it “became younger” and every year becomes “younger” and grows with a geometric progression.

This disease is in third place after cancer and cardiovascular. People are increasingly ill, even though medicine is improving day by day. The growing trend of cardiovascular, cancer, mental illness, and diabetes is observed not only in our country but also in more developed countries such as America. Table 1 presents some correlation indicators for the selected study object – DIABETES.

In the early stages of project development, it is often necessary to perform Exploratory data analysis (EDA) in order to identify patterns that identify the data. Data visualization helps to present large and complex datasets in a simple and visual way. Figure 3-4 shows the patterns between DIABETES_CrudePrev and other features.

The distribution density of two variables gives a gradient (Fig. 5), which in its direction indicates the direction of the greatest growth of a quantity whose value varies from one point of space to another and in magnitude is equal to the rate of growth of this value in this direction. The graphs presented in Figure 5 confirm the results of the studies. You can make sure that density

of distribution of indicators DIABETES_CrudePrev and BPHIGH_CrudePrev, STROKE_CrudePrev, LPA_CrudePrev are better than DIABETES_CrudePrev and CASTHMA_CrudePrev.

Table 1. Correlation coefficients.

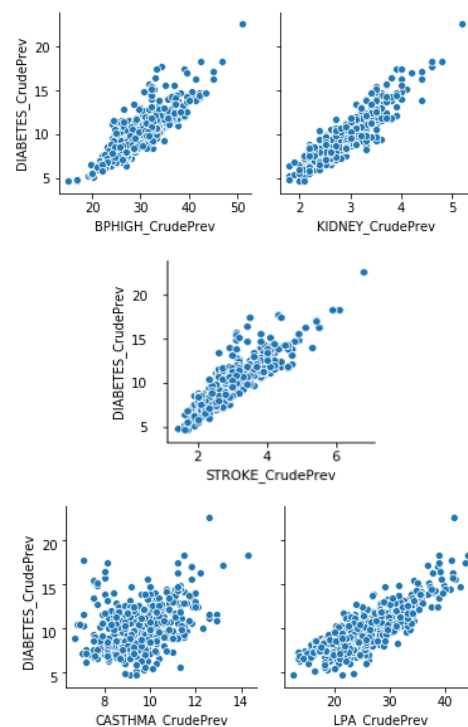

Fig. 3. Dependence between diabetes and other diseases.

To solve the problem of machine learning, the Scikit library was used. This library provides a wide variety of algorithms for (un)supervised learning.

The developed method [12] receives some elements on input, such as model, test data, name of the column for prediction, the names of the columns based on which the prediction is made, the desired accuracy of prediction (as absolute values), the way the test data is prepared.

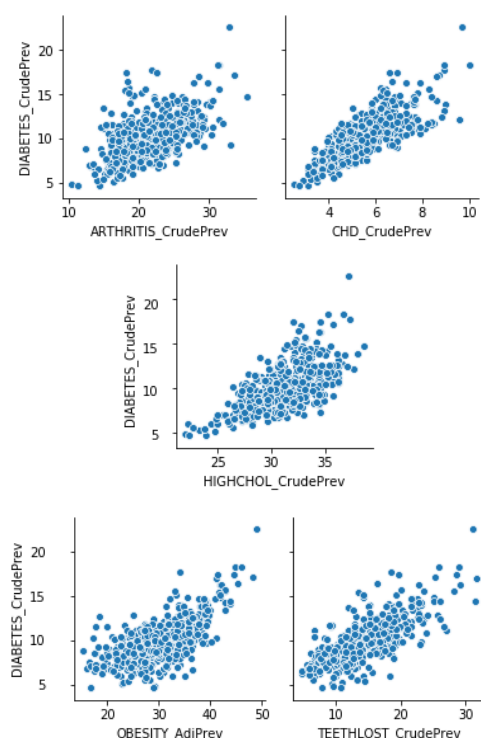

Fig. 4. Dependence between diabetes and other diseases.

Fig. 5. Density distribution by parameters.

Also, the method of least squares for testing was used, which is defined as $1 - \frac{u}{v}$, where u is the sum of squared errors of prediction:

$$\sum_{i=0}^n (y_i \text{ actual} - y_i \text{ predict})^2, \quad (12)$$

and v is the total sum of squares of the difference between the mean of the dependent variable and the exact value:

$$\sum_{i=0}^n (y_i - y_i \text{ average})^2 \quad (13)$$

As a result, a versatile method for estimating the quality of predicting was developed, that can be used to create green IT. Additionally, a deviation of $\pm 1\%$. As a result of the research, it is determined that various methods of data mining predict the prevalence of chronic diseases with sufficient accuracy.

Conclusions

A correlation-regression analysis of chronic disease statistics was conducted based on the data set of the American Centers for Disease Control and Prevention (CDC). Models for Naive Bayes classifiers are developed. The support vector machine was used for classification and regression analysis.

An exploratory data analysis was performed, in which it was discovered unexpected dependencies between diagnosed diabetes mellitus among adults and high blood pressure, kidney disease, coronary artery disease and loss of all teeth.

As a result of the researches of the mentioned algorithms of data mining, models and methods were developed to establish the impact of some chronic diseases on others.

To increase the reliability of the results using the proposed models and methods, it is necessary to increase the amount of data. The studies conducted provide the basis for the practical design of energy efficient data processing centers.

Enhancement of alkali-activated slag cement concretes crack resistance for mitigation of steel reinforcement corrosion

*Pavlo Krivenko, Oleh Petropavlovskiy, Oleksandr Kovalchuk, Igor Rudenko, and Oleksandr Konstantynovskyi**

Kyiv National University of Construction and Architecture, Scientific Research Institute for Binders and Materials, 31 Povitroflotskyi Ave., Kyiv, 03037, Ukraine

Abstract. The paper is devoted to mitigation of steel reinforcement corrosion in alkali-activated slag cement (further, AASC) concretes, based on soluble sodium silicates (further, SSS's), obtained from high consistency concrete mixes. Enhancement of AASC fine concretes crack resistance due to modification by complex shrinkage-reducing additives (further, SRA's) based on surfactants and trisodium phosphate $\text{Na}_3\text{PO}_4 \cdot 12\text{H}_2\text{O}$ (further, TSP) was proposed for mitigation of steel reinforcement corrosion. SSS's were presented by sodium metasilicate (silica modulus 1.0, dry state) and water glass (silica modulus 2.9, density 1400 kg/m^3). In case of sodium metasilicate the application of SRA composition "ordinary portland cement clinker – TSP – sodium lignosulphonate – sodium gluconate" provides enhancement of crack resistance starting from early age structure formation with restriction of drying shrinkage from 0,984 to 0,713 mm/m after 80 d. The effect is caused by reduction of water and by higher volume of crystalline hydrates. In turn, SRA presented by compositions "TSP – glycerol" and "TSP – glycerol – polyacrylamide" provide enhancement of AASC fine concretes fracture toughness during late structure formation with increasing ratio of tensile strength in bending to compressive strength up to 37 – 49 % if compare with the reference AASC when water glass is used.

1 Introduction

The actuality of green materials implementation is due to their conformity with modern tendencies of building industry development in the part of efficient consumption of raw materials and energy resources, responsible attitude to ecology of the environment, while ensuring high quality, functionality and durability of building materials. Thus eco-efficient composite cements, based on slag, zeolite, fly-ash, limestone as well as microsilica, ensure high early strength of mortars [1, 2]. Application of a highly dispersed chalk as an additive in these cements increases strength, waterproof and freeze-thaw resistance of concretes [3, 4].

Alkali-activated slag cement (further, AASC) are the most perspective environmentally friendly one in view of the modern tendencies of sustainable development. The ecological benefits of AASC's are caused by reduction of CO_2 emission while consumption of by-products as well as waste products [5, 6, 7]. AASC mortars and concretes are characterized by increased strength [8, 9], heat resistance [10, 11], corrosion resistance [12, 13], freeze-thaw resistance [14, 15] and waterproof [16] in comparison with analogues based on traditional clinker cements.

Thus, AASC's are effective for strategic construction objects with special destination (fortifications, sea ports, bridge foundations, tunnels, etc.), which must be exploited in various aggressive mediums. AASC based

on soluble sodium silicates (further, SSS) is the most interesting type, first of all due to comparative strength benefits. This fact is relevant for special concretes.

High durability of AASC reinforced concretes obtained from harsh (low consistency) concrete mixes was already proved by long-term exploiting experience [17-21]. However, the modern requirements to high consistency fresh concretes are governed by practice. This way the disturbance of reinforcement passive state can be caused by changes in hardened concrete structure. The means for protection of reinforcement in such AASC concretes must be developed. One of decisions is the enhancement of crack resistance during all stages of service life cycle.

AASC concretes along with high strength are characterized by increased drying shrinkage and fracturing [22, 23, 24] due to high content of gel during initial structure formation. The drying shrinkage causes heterogeneous structure of concrete during further structure formation and as a result the unstable characteristics of artificial stone [25].

There are number of means to prevent fracturing, for example fiber reinforcement of concrete [26]. It's also well known, that surfactants allow regulating consistency while ensuring high strength of concrete. Diminution of drying shrinkage is a result of decreased water. Most of surfactants are ineffective for AASC and therefore the principles for their choice were proposed [27, 28]. The maximum water-reducing effect in this

* Corresponding author: alexandrkp@gmail.com

case can be provided by sodium lignosulfonate [29], sodium gluconate [30], polyhydric alcohols [27], etc. Triatomic alcohol glycerol and polyacrylamide are the most perspective modifiers of AASC's based on water glass. These admixtures bind surface groups of silicic acid oligomers by means of hydrogen links while ensuring high strength, waterproof and elasticity of AASC mortars and concretes [31, 32, 33].

Another mean for drying shrinkage mitigation is complex application of admixtures and additives. It was shown the effectiveness of salts-electrolytes, like Na_2SO_4 [34], and by-pass cement kiln dust, which typical components are free CaO and salts (KCl, NaCl, K_2SO_4 , Na_2SO_4 , CaSO_4 , K_2CO_3 , Na_2CO_3 , CaCO_3 , etc.) [35, 36]. Trisodium phosphate $\text{Na}_3\text{PO}_4 \cdot 12\text{H}_2\text{O}$ (further, TSP) is well-known retarder of AASC setting time [37, 38]. TSP also ensures effect of water glass stabilizer to prevent early coagulation while interaction with slag in AASC [39]. Moreover, TSP can be used as inhibitor of steel reinforcement corrosion due to formation of chemical stable products like hydroxyapatite $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ [37] with formation of a dense protective film on metal surface [40, 41], increasing polarization resistance of rebar [42, 43] as well as decrease of capillary pore network with time [44].

The fundamentals of mineralogy and chemistry can give some explanations concerning effect of the mentioned compounds on the structure of AASC stone, namely about isomorphism with replacing of silicate or aluminate anion, formation of solid solutions or additional crystalline formations, which reduce the proper deformations [45]. These compounds can be used as complex modifiers of AASC.

Increasing of AASC's crack resistance in consequence of drying shrinkage mitigation can also be accomplished by increasing crystallinity of hydrated phases when using high-calcium additives such as ordinary portland cement clinker (further, OPC clinker) [18, 46] or lime [47, 48].

The above results allows to predict increasing of AASC crack resistance due to complex shrinkage-reducing additives (further, SRA's) in the system "additives – surfactants". Specified method was proposed for mitigation of steel reinforcement corrosion in high consistency AASC concretes, modified with SRA's based on salts-electrolytes, i.e. Na_2SO_4 and NaNO_3 [24, 49, 50]. The effectiveness of these SRA's was explained by their co-acting in crystallization processes, alteration of porous structure as well as morphology of hydrated phases.

The aim of this research was to ensure crack resistance of AASC concretes, based on SSS and plasticized by SRA's, for mitigation of steel reinforcement corrosion during all stages of structure formation.

2 Raw Materials and Methods

Five compositions of AASC based on SSS were used:

- #1 - the reference AASC based on sodium metasilicate (ground granulated blast furnace slag

(further, GBFS) – 88.20 %, sodium metasilicate – 11.80 % (3.91 % by Na_2O));

- #2 - AASC based on sodium metasilicate, modified by SRA composition "OPC clinker – TSP – sodium lignosulphonate – sodium gluconate" (GBFS – 83.80 %; sodium metasilicate – 11.20 % (3.91 % by Na_2O); SRA – 5 %);

- #3 - the reference AASC based on sodium water glass (GBFS – 71.74 %; water glass, modified by TSP – 28.26 %);

- #4 - AASC based on sodium water glass, modified by SRA composition "TSP – glycerol" (GBFS – 71.65 %; water glass, modified by TSP – 25.65 %, glycerol – 2.70 %);

- #5 - AASC based on sodium water glass, modified by SRA composition "TSP – glycerol – polyacrylamide" (GBFS – 71.65 %; water glass, modified by TSP – 25.65 %, glycerol – 2.69 %, polyacrylamide – 0.01 %).

GBFS, basicity modulus = 1.1, content of glass phase = 84 %, specific surface = 450 m^2/kg (by Blaine), was used as AASC aluminosilicate component.

SSS were used as AASC alkaline components:

- five-water sodium metasilicate ($\text{Na}_2\text{SiO}_3 \cdot 5\text{H}_2\text{O}$), dry state;

- sodium water glass, modulus $M_s = 2.9$, density = 1400 kg/m^3 .

Surfactants in SRA's were presented by:

- sodium lignosulphonate (further, LST) according to CAS 8061-51-6 ($\text{pH} \geq 8.5$) and sodium gluconate according to CAS 527-07-1 (for AASC's based on sodium metasilicate);

- glycerol according to CAS 56-81-5 and polyacrylamide according to CAS 9003-05-8 (for AASC based on water glass).

Additives in SRA's were presented by:

- OPC clinker (CaO – 66.15 %; SiO_2 – 22.61 %; Al_2O_3 – 5.29 %; Fe_2O_3 – 3.93 %; MgO – 0.84 %; Na_2O – 0.15 %, K_2O – 0.98 %, SO_3 – 0.50 %), specific surface = 450 m^2/kg (by Blaine);

- $\text{Na}_3\text{PO}_4 \cdot 12\text{H}_2\text{O}$ (TSP) according to CAS № 7601-54-9.

The content of TSP was accepted experimentally while providing allowable initial setting time (not less 15-20 min). TSP was dissolved in water glass to provide density = 1400 kg/m^3 .

Normal consistency of cement pastes and setting time were determined according to the national standard of Ukraine DSTU B V.2.7-185:2009.

The standard quartz sand in accordance with EN 196-1 was used as a fine aggregate to determine strength and proper deformations of AASC concrete.

Cement pastes and fine concrete mixes were prepared in mixer Hobart type.

Water-reducing effect of SRA's was evaluated by decreasing W/C ratio in AASC/sand mixes (1:3) with slump flow = 106-115 mm on flow table according to the national standard of Ukraine DSTU B V.2.7-187:2009. The strength and proper deformations of AASC fine concrete were determined on specimens 40x40x160 mm. After manufacturing and hardening in forms with an insulated surface for 1 day, the samples were stored for 7 d under the normal conditions ($t = 20 \pm 2^\circ\text{C}$, R.H. = $95 \pm 5\%$). Then the samples were stored over

saturated solution of potassium carbonate (NH_4NH_3) at $t = 20 \pm 2$ °C till the control age. The length of samples after 1 d was taken as the initial one (zero) in calculations.

Analysis of elastic-deformed state of AASC concretes under load was realized by bending test while determination of deformations up to destruction of samples (Fig. 1). Fracture toughness was estimated by the values of tensile strength in bending to compressive strength ratio. This method allows to determine effect of cement composition as well as structural features of cement on the values of deformation and destruction [51].

Fig. 1. Testing of samples under load.

Research of microstructure of artificial stone was carried out by differential-thermal analysis (DTA) and electronic microscope with micro analyzer.

3 Results and discussion

Effect of SRA's in the system "additives – surfactants" on crack resistance of AASC fine concrete (further, concrete) are shown on examples.

3.1 Enhancement of crack resistance of alkali-activated slag cement concrete based on sodium metasilicate

Characteristics of the reference AASC (without SRA): normal consistency of cement pastes – 21.67 %, initial setting time – 45 min, final setting time – 45 min. The tensile strength in bending / compressive strength of AASC concrete (W/C ratio = 0.29): 5.04 / 28.8 MPa (2 d), 6.1 / 40.0 MPa (7 d) and 7.5 / 50.3 MPa (28 d).

Effect of SRA composition "OPC clinker – TSP – LST – sodium gluconate" on drying shrinkage of AASC concrete was researched (Fig. 2). The reference AASC concrete is characterized by high drying shrinkage during the initial structure formation. SRA composition "OPC clinker – TSP – LST – sodium gluconate" ensures formation of AASC concrete with preferable structure

and mitigation of drying shrinkage from 0,984 down to 0,713 mm/m after 80 d.

Fig. 2. Drying shrinkage of alkali-activated slag cement fine concrete.

SRA provides deceleration of AASC setting time as well. For example, SRA based on TSP provides prolongation of initial setting time from 45 up to 55 min and final setting time from 60 to 68 min. Increasing strength of modified AASC concrete regarding to the reference one while decreasing W/C ratio from 0.29 to 0.27 was fixed. The tensile strength in bending / compressive strength of the modified AASC concrete: 6.6 / 30.2 MPa (2 d), 6.4 / 41.2 MPa (7 d) i 10.2 / 47.8 MPa (28 d).

The enhancement of AASC concrete properties can be provided not only by water-reducing effect of SRA, but also due to effect on further structure formation. The features of AASC structure, modified by SRA, were fixed by DTA (Fig. 3) and electronic microscopy (Fig. 4, 6) as well as by microzond analysis (Fig. 5, 7).

Fig. 3. DTA results of alkali-activated slag cement hydrated during 28 d: 1 – reference; 2 – modified by shrinkage-reducing admixture.

According to DTA, the phase composition of hydrated AASC in absence of SRA (Fig. 3) is represented low-calcium hydrosilicates CSH(B). The endothermic effect at $t = 150$ °C is determined by their dehydration and exothermic effects at $t = 840$ °C are determined by recrystallization into wollastonite. Endothermic effects at $t = 150$ and 700 °C (dehydration) and exothermic effect at $t = 800$ °C confirm formation of slightly crystallized calcium hydrosilicates like gyrolite $2\text{CaO} \cdot 3\text{SiO}_2 \cdot 2\text{H}_2\text{O}$. Slightly crystallized sodium hydroaluminosilicates like gmelinite $(\text{Na}_2\text{Ca}) \cdot \text{Al}_2\text{Si}_4\text{O}_{12} \cdot 6\text{H}_2\text{O}$ (endothermic effect at

$t = 530^\circ\text{C}$) are formed in hydration products besides hydrosilicates.

Fig. 4. SEM images of the reference alkali-activated slag cement after 28 d of hydration.

According to electron microscopy (Fig.4), gel-like calcium hydrosilicates (CSH(B), $2\text{CaO} \cdot 3\text{SiO}_2 \cdot 2\text{H}_2\text{O}$) and globular formations of sodium hydroaluminosilicate ($(\text{Na}_2\text{Ca}) \cdot \text{Al}_2\text{Si}_4\text{O}_{12} \cdot 6\text{H}_2\text{O}$) are identified in the reference AASC (Fig. 5).

Fig. 5. Probe analysis results of the reference alkali-activated slag cement after 28 d of hydration.

Structure of the modified AASC is represented by hydrates with a higher crystallization in comparison with the reference AASC (Fig. 3). Displacement of exothermic effect from $t = 840$ to 850°C is evidence of low-calcium hydrosilicates CSH(B) with higher crystallinity. Displacement of endothermic effect to higher temperature ($t = 550^\circ\text{C}$) as well as exothermic effect at $t = 915^\circ\text{C}$ ensure formation of gmelinite $(\text{Na}_2\text{Ca}) \cdot \text{Al}_2\text{Si}_4\text{O}_{12} \cdot 6\text{H}_2\text{O}$ with a higher degree of crystallization.

Fig. 6. SEM images of alkali-activated slag cement, modified by shrinkage-reducing admixture, after 28 d of hydration.

Fig. 7. Probe analysis results of alkali-activated slag cement, modified by shrinkage-reducing admixture, after 28 d of hydration.

The microstructure of modified AASC was investigated. The data indicate hydrosilicates and hydroaluminates with a higher degree of crystallization (Fig. 6) as well as thin plate pyramidal cristalls of hydroxyapatite $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ [37] (Fig. 7).

3.2 Enhancement of crack resistance of alkali-activated slag cement concretes based on sodium water glass

The effect of SRA based on TSP and surfactants on enhancement of crack resistance of AASC mortars based on sodium water glass was investigated.

The AASC, modified only by TSP (further, the reference AASC), was characterized by initial setting time – 19 min, final setting time – 21 min. The flexural strength / compressive strength of AASC concrete correspond to values of 4.6 / 25.5 MPa (3 h), 5.0 / 32.3 MPa (1 d), 7.2 / 66.5 MPa (7 d), 8.7 / 86.8 MPa (28 d). The 28 d ratio between tensile strength in bending and compressive strength (further, $R_{\text{bend}}/R_{\text{comp}}$) is 0.102.

The initial setting time can be prolonged up to 60 min and the final setting time to 70 min due to modification of the reference AASC by glycerol (2.70 %). SRA composition “TSP – glycerol” ensures water glass, modified by TSP/GBFS ratio diminution to 0.37 due to plasticizing effect. Insignificant deterioration of modified AASC early strength was fixed. Thus the values of flexural strength / compressive strength are: 3.8 / 19.2 MPa (3 h), 5.0 / 29.5 MPa (1 d). However strength of the modified AASC becomes equal to the reference one in 7 and 28 d. The ratio $R_{\text{bend}}/R_{\text{comp}}$ increases up to 0.140 after 28 d.

Effect of SRA composition “TSP – glycerol – polyacrylamide” on properties of AASC was also researched. The content of glycerol was 2.69 % and polyacrylamide – 0.01 %. This SRA ensures AASC, characterized by initial setting time 58 min and final – 66 min while water glass, modified by TSP/GBFS ratio decreases from 0.4 down to 0.38.

Effects of SRA compositions “TSP – glycerol – polyacrylamide” and “TSP – glycerol” on AASC concrete strength are almost similar. Only insignificant deterioration of early strength was fixed. The flexural

strength / compressive strength of modified AASC concrete corresponds to values of 4.0 / 22.4 MPa (3 h), 5.4 / 31.8 MPa (1 d), 8.8 / 69.0 MPa (7 h), 13.0 / 85.5 MPa (28 d). The ratio $R_{\text{bend}}/R_{\text{comp}}$ increases up to 0.152 after 28 d. Thus SRA causes maintenance of $R_{\text{bend}}/R_{\text{comp}}$ ratio on 37-49 % in comparison with the reference AASC concrete. This is evidence of higher fracture toughness as well as crack resistance during late structure formation [51].

The features of AASC structures, modified by SRA of the mentioned compositions, were investigated by electronic microscopy (Fig. 8, 9, 10).

Fig. 8. SEM images of the reference alkali-activated slag cement after 28 d of hydration.

Unlike to the reference AASC (Fig. 8), SRA “TSP – glycerol” ensures increasing volume of hydrates presented by submicrocrystalline compounds like spherulites as well as united into agglomerates and block-agglomerates (Fig. 9). SRA composition “TSP – glycerol – polyacrylamide” increases depressiveness of hydrated phases and ensures increasing of phase’s boundary area in artificial stone (Fig. 10).

Fig. 9. SEM images of alkali-activated slag cement, modified by shrinkage-reducing admixture composition “trisodium phosphate – glycerol”, after 28 d of hydration.

Specified structures of modified AASC concretes testify their higher ability for relaxation and dissipation of outside energy.

Diagrams of AASC mortars elastic-deformed state in co-ordinates “stress – deformations” are shown on fig. 11, 12, 13. Some increasing of rigidity of AASC concrete, modified by SRA’s, during initial load stage was fixed. Increasing of tangent angle for AASC concretes, modified by SRA compositions “TSP –

glycerol” and “TSP – glycerol – polyacrylamide”, in comparison with the reference AASC concrete from 65° (Fig. 11) to 66° (Fig. 12) and 67° (Fig. 13) agreeably confirm this fact.

Fig. 10. SEM images of alkali-activated slag cement, modified by shrinkage-reducing admixture composition “trisodium phosphate – glycerol – polyacrylamide”, after 28 d of hydration.

Fig. 11. Deformations of the reference alkali-activated slag cement concrete under load.

Fig. 12. Deformation of alkali-activated slag cement concrete, modified by shrinkage-reducing admixture composition “trisodium phosphate – glycerol”, under load.

SRA ensures higher specific micro cracking (W_n) under subsequent gradual increasing of load until destruction point of samples. Increasing of load resistance for AASC concrete, modified by SRA compositions “TSP – glycerol” and “TSP – glycerol – polyacrylamide” from 3310 N (for the reference AASC concrete) up to 3680 N and 3720 N agreeably was fixed. As well AASC concrete, modified by SRA’s, can be characterized by increased specific energy of elastic deformation. Increasing in area of sections W_u by 39-

52 % and maintenance of total bending deflection of samples up to 310 μm confirm this fact.

Fig. 13. Deformation of alkali-activated slag cement concrete, modified by shrinkage-reducing admixture composition “trisodiumphosphate – glycerol – polyacrylamide”, under load.

Both mentioned SRA’s ensure enhancement of fracture toughness, crack resistance and higher ability to deformation of AASC concretes.

Conclusion

1. The crack resistance enhancement of alkali-activated slag cement concretes, based on soluble sodium silicates and obtained from high consistency concrete mixes, was shown from initial up to late stages of structure formation. It was realized due to shrinkage-reducing admixtures based on trisodium phosphate and surfactants. This way the higher crack resistance ensures mitigation of steel reinforcement corrosion.
2. Modification of alkali-activated slag cement fine concretes by shrinkage-reducing admixture composition “ordinary portland cement clinker – trisodium phosphate – sodium lignosulphonate – sodium gluconate” causes less drying shrinkage during early age structure formation and mitigation of drying shrinkage from 0,984 to 0,713 mm/m after 80 d as well as enhancement of crack resistance during late structure formation. Effect of shrinkage-reducing admixtures is caused by reduction of water content and increasing crystallinity of AASC hydrates.
3. Shrinkage-reducing admixtures compositions “trisodium phosphate – glycerol” and “trisodium phosphate – glycerol – polyacrylamide” provide fracture toughness enhancement of alkali-activated slag cement fine concretes during late stages of structure formation. As result, the ratio between tensile strength in bending and compressive strength of AASC concrete can be increased up to 37 – 49 % when water glass is used. At that increasing of bending deflection under load ensures higher elasticity of modified alkali-activated slag cement fine concretes. Specified effects of the shrinkage-reducing admixtures are caused by increasing depressiveness of gel-like hydrates, providing redistribution of stresses in artificial stone and thereby advanced fracture toughness under load.

Authors express their gratitude to the Ministry of Education and Science of Ukraine for financial support of the research, that was performed in the framework of budget funding, as

well as for the development of the theme of research according to the program of scientific cooperation COST Action CA15202 “Self-Healing concrete: the path to sustainable construction” of the European Union’s framework program HORIZON 2020.

Abstract. Sustainable development of construction materials is directly related to research on the processes of hydration of binders. Builders need better types of cement, with lower cost and energy consumption in production. The development of spin chemistry methods allows us to consider the processes of hydration and structure formation of binders from the spin state of the elements involved in chemical reactions. Magnetic interactions have a significant effect on the spin dynamics and the control of the spin multiplicity of radical pairs. The practical implementation of magnetic effects on a binder can be carried out in various ways. However, a long-term impact can be achieved only by introducing ferromagnetic substances into the binders. In the paper presented the results of a study of the influence of the characteristics of finely dispersed powdered ferromagnetic additives on the strength characteristics of cement. Ferromagnetic additives regulate the behavior of the reactants during rotation during the hydration of the binders due to magnetic interactions and control the reactivity of the chemical reaction. A comparative analysis revealed that it is most expedient to use as powdery ferromagnetic additives are the waste from mining and processing enterprises of the Krivorozhsky field. The work investigated the magnetic and dispersed characteristics of 12 different dust. The experiments showed that the origin of dust and the method of their capture are determined their magnetic characteristics. Preparation of samples with the dust and determination of the strength characteristics of cement were carried out by standard methods. The results obtained made it possible to reveal the laws of the effect of the dispersed and magnetic properties of various dust on the degree of activation of binders.

1 The problem and its relationship with scientific and practical tasks

Cement is one of the most essential currently used building materials. The main components for the production of cement are clay and limestone. In the process of co-firing limestone and clay, a clinker obtained consisting of four primary minerals: alite, belite, tricalcium aluminate, and tetracalcium aluminato ferrite. Cement is a product of joint grinding of clinker and gypsum, which introduced to regulate the setting time.

After mixing the cement with water, is formed a cement paste, which begins to harden after 40 minutes and finally turns into a cement stone after 6 hours. Cement hardening occurs due to hydrolysis reactions and subsequent hydration of its components. After the influence of water on the surface of cement formed particles of calcium hydroxide, calcium silicate hydrate, and calcium aluminate hydrate. In the process of hardening, neoplasms pass from a colloidal state to a fine crystalline one. Microcrystals gradually grow together. The processes of gel formation, crystallization, and

compaction lead to the transformation of cement paste into an artificial high-strength stone material.

The currently existing theories of hardening binders (A. Le Chatelier, V. Michaelis, A. A. Baykov, and others.) primarily develop physicochemical ideas about the mechanism of formation of hydrated compounds and hardening of mixtures of binders with water when they interact with each other. Moreover, the interpretation of the processes occurring during the hardening of the cement paste is based solely on charges. It assumed that during the solidification of binders, the forces of electrostatic nature are decisive since the particles of the new phase are not neutral. Because of the orientation of the dipoles of the dispersion medium adsorbed on their surface, they acquire a particular charge.

Despite numerous studies, this approach has not yet been able to reveal the true nature of the forces leading to the strengthening of the structure and the synthesis of the strength of cement stone and to create a unified and universally accepted theory of hardening of cementitious systems.

2 Analysis of research and publications

The intensive development of spin chemistry methods allowed us to consider the processes of hydration and structure formation of binders in juxtaposition with the spin state of the elements involved in chemical reactions [1]. In [2], were presented experimental results that prove the presence of radical reactions during the hardening of the cement. In [1, 2] was shown that cement is paramagnetic substances, and the appearance of paramagnetic centers in them explained by the appearance of spin-orbitals populated by a single electron in an atomic or molecular system. The method of electron paramagnetic resonance made it possible to quantify the paramagnetic properties of cement and their change during hardening.

In [5] was shown that the number of paramagnetic centers in cement increases up to 3 days of hardening and then decreases to a level below the initial value. According to the results of studies [3, 4], the concentration of paramagnetic centers in cement is high and can reach 1022 spin/g. The authors found that cement with a higher concentration of paramagnetic centers has higher strength characteristics. Research [5] has shown that cement hardens due to the recombination of paramagnetic centers, which leads to the formation of new phase states, the presence of which contributes to the hardening of the cement mortar and the creation of cement stone.

In [6] was shown that magnetic interactions have a significant influence on the spin dynamics and the control of the spin multiplicity of radical pairs. In this case, magnetic interactions, without affecting the chemical reaction itself, switch it from spin-forbidden channels to spin-allowed ones, regulating the spin behavior of the reagents, replacing non-reaction channels with reaction ones. [6]. Thereby, the reactivity of the chemical reaction is regulated.

It can be argued that magnetic fields can affect the chemical processes that occur during the hydration of binders because of the presence of radical reactions during the hardening of the cement.

Previously it was researched the magnetic activation of water for binder [7], activation of a binder by magnetic treatment during grinding [8], and in the interval between grinding and mixing the binder with water [9].

The method of activation by magnetizing the binder itself [8, 10 – 12] has the disadvantage that.

In most cases have low magnetizability, which also lasts a relatively short time. Thus, this method has a weak effect on the course of hardening reactions of binders.

A method for activating a binder by magnetizing a cement paste has developed in many embodiments. For activation, fields of various intensities were used, as well as variable and pulsating fields. Of all known, this method gives the best results [10] due to the relatively more powerful magnetic fields superimposed on the hardening mixture, as well as the stability of these fields. However, it also has drawbacks that affect the strength characteristics of the binder. First of all, this is a short time of exposure to magnetic fields on the binder. In most cases, it does not exceed 15 to 30 minutes, and this is only a small fraction of the total binder curing time.

Accordingly, the effect of activation of the binder decreases.

In addition to the above disadvantages, all of the above methods of activating binders have one more. The binder can be activated only at the place of preparation of concrete or mortar. At the same time, the manufacturing technology of building products is complicated and changed, the time spent on manufacturing specific products increases, the need for additional equipment and specially trained personnel arises, and the likelihood of errors in choosing the magnitude of the magnetic field strength, the time of its exposure and the dosage of additional components increases.

3 Formulation of the problem

The described disadvantages are absent if the binders activated by introducing into their composition a pre-magnetized ferromagnetic powder. The effectiveness of this method because by the fact that the influence of magnetic fields occurs at all stages of the creation of a binder and its hardening, starting from co-grinding cement with powder and ending with long hardening periods of 1 year or more. In this case, each stage contributes to the increase in strength. It is advisable to use powdered ferromagnetic production waste as additives to reduce the cost of activation of binders. As such substances, we proposed the use of dust generated at various stages of iron ore enrichment. At the same time, this allows the disposal of dusty waste from mining and processing plants to sustain the environmental situation. In table 1 is given the characteristics of the enrichment products of various deposits.

Table 1. Characterization of the magnetic properties of concentrates obtained from ores of various deposits [13, 14].

Sample	Density, – 10 ³ kg/m ³	Magnetization, – 10 ³ , A/m	
		Maximum	Residual
Magnetite of the Akkerman field	4.2	45.7	23.0
Magnetite of the Krivorozhsky deposit	4.7	189.0	60.5
Maghemite of the Vyatka field	4.0	119.0	42.5
Magnetite of the Vysokogorsky deposit	4.8	196.0	22.0
Magnetite of the Lebedinsky deposit	–	80.5	20.0
Magnetite of the Tashtagol deposit	–	64.5	12.5
Magnetite of the Kremenchuk field	–	72.0	22.3
Magnetite of the Sokolovsky deposit	–	105.4	-
Magnetite of the Kachkanarsky deposit	–	126.0	37.0

The table data shows that the largest residual magnetization has the magnetite of the Krivorozhsky deposit. Therefore, the most effective will be the addition of dusty wastes of this field.

In table 2 is shown the chemical and mineral

composition of the dust concentrate from the mining and processing enterprises of Krivbass.

After agglomeration and pelletizing of the concentrate in the dust, the amount of bound calcium oxide and carbon increases. In table 3 is shown the chemical composition of the sinter dust.

Table 2. Chemical and mineral composition of the dust of concentrate of mining and processing plants of Krivorozhsky deposit [13, 14].

Chemical composition, %	Components	Content
	Fe	65.2
	SiO ₂	8.17
	Al ₂ O ₃	0.15
	CaO	0.11
	MgO	0.4
	P	0.01
	S	0.014
	other	0.8
Mineral composition, %	magnetite	64.3
	hematite, martite, hydroxides	4.35
	siderite, silicates	2.2

Table 3. The chemical composition of the dust of the sinter machine [15].

Components	Content, %
FeO	9 – 19
Fe ₂ O ₃	45 – 60
SiO ₂	6.5 – 10
Al ₂ O ₃	0.5 – 1.5
CaO	6.3 – 9
MgO	0.5 – 1.5
MnO	0.2 – 0.3
P ₂ O ₅	0.03 – 0.05
S	0.2 – 0.5

In table 4 is given the dispersed composition of the dust.

Table 4. The dispersed composition of the dust of mining and processing plants.

Particle diameter, μm	Particle mass, %
4	3.2 – 5.1
4-6.3	2.1 – 2.3
6.3-10	4 – 5
10-16	8.3 – 8.7
16-25	10 – 12
25-40	13 – 15
40-63	12 – 15
63-100	20 – 22.5
100-400	14.3 – 16.2

Research under a microscope shows that particles of iron ore dust are irregular in shape with sharp edges. Most particles have color from brown to black. In the total mass, depending on the stage of enrichment, the color of the dust changes from red to black.

The highest dust formation occurs at the following stages of enrichment: during magnetizing roasting of the ore, during transportation of concentrate, during roasting of pellets, during agglomeration of the concentrate.

Because this, did study four dust groups:

- dust generated by magnetizing roasting of the ore;
- dust generated during transportation of the concentrate;
- dust generated during the firing of pellets;
- dust formed during the agglomeration of the concentrate.

Dust generated after magnetizing roasting of ore during transportation of concentrate and roasting pellets is captured either in cyclones or in an aqueous medium. During dust collection on dust are not superimposed electromagnetic fields. For a complete study of the properties of these dust, it proposed to study them in an unmagnified state and magnetized in a constant magnetic field with a strength of 75 kA/m.

The dust collection of sinter production carried out in electrostatic precipitators. During the capture process, on this type of dust are superimposed high-intensity electromagnetic fields. Given this, the determination of the dust properties of sinter production carried out without additional magnetic treatment.

Each type of dust is assigned a number, which later used on the figures of this article. In table 5 is given the name of dust and their ID number.

Table 5. The identification numbers of different types of dust.

Dust ID number	Type of dust
1	not magnetized dust from the collector generated by magnetizing roasting of the ore
2	magnetized dust from the collector generated by magnetizing roasting of the ore
3	not magnetized dust from the scrubber generated by magnetizing roasting of the ore
4	magnetized dust from the scrubber generated by magnetizing roasting of the ore
5	not magnetized dust of concentrate
6	magnetized dust of concentrate
7	not magnetized dust generated during the firing of pellets
8	magnetized dust generated during the firing of pellets
9	the dust of the sintering machine from cyclone
10	the dust of the sintering machine from electrostatic precipitator zone I
11	the dust of the sintering machine from electrostatic precipitator zone II
12	the dust of the sintering machine from electrostatic precipitator zone III

4 Statement of material and results

The dust research methodology includes the following components: sampling and preparation methods and methods for determining dust properties.

Sampling and preparation of samples carried out according to the following procedure.

A shovel of non-magnetic material used to extract 20 kg of dust from industrial dust collectors. Each sample was placed in its plastic bag and then in an aluminum tank. Then the sample was transported to the laboratory. Further processing of dust was carried out far from sources of electromagnetic radiation.

In the laboratory, the sample was thoroughly mixed and then quartered. Stirring and quartering continued until

the amount of material in the sample were reduced to 100 g. On a sheet of clean white paper of 350×350 mm in size, the sample was mixed and divided into ten equal parts using a plastic spatula.

In one of the formed parts of the dust was immersed a glass rod pre-moistened with glycerin. Then, the stick with adhering dust was placed in a cell with glycerin and mixed until was obtained a homogeneous suspension. Similarly, it was prepared suspensions from the remaining parts of the dust. Each cuvette was alternately placed in the installation to study the properties of dust.

Dust studied in a specially designed setup (Fig. 1) that consists of a digital microscope and a system of electromagnets mounted on a stage. An energy source feeds the orientation coils, as well as the illuminator time relay, so the control circuit provides the simultaneous switching on and off of the coil measurement system and the electronic stopwatch.

Fig. 1. Installation for determining the magnetic and dispersed characteristics of additives. 1 – digital microscope; 2 – a cuvette with glycerin and dust; 3 – orientation coil system; 5 – laptop with control program; 6 – the digital coil of the power control unit.

A cuvette (Fig. 1) with glycerin and test dust was placed under the microscope lens, after which the orientation system of the coils turned on. In this case, a uniform magnetic field is created in the cuvette, orienting the magnetic particles. Then, using a time relay, the measuring system of coils and the electronic stopwatch are simultaneously switched on. After a particular time, the system turns off.

The rotation angle of all particles is fixed on the photograph at the same speed to eliminate the error of visual observation. First is photographed the arrangement of particles oriented perpendicular to the measuring field along the orientation. Then, using the time relay, the measuring field is switched on for a while and is photographed a new arrangement of particles. Two photographs determine the angle of rotation of particles β , rotation time t , and particle sizes, which makes it possible to decide on magnetic characteristics (Fig. 2). From each sample are determined the parameters of at least one hundred particles.

In the research of dust were determined the fractional composition, the fraction of dust particles with magnetic properties, the average magnetic moment of particles of one fraction, and the average magnetization of all dust.

The dispersed composition was determined by the following fractions: less than 1.4 μm ; 1.4 – 4.2 μm ; 4.2 – 7.0 μm ; 12.6 – 15.6 μm ; 15.6 – 31.2 μm ; 31.2 – 46.8 μm ; 46.8 – 62.0 μm ; more than 62.0 μm .

Fig. 2. Dust in the installation for determining magnetic and dispersed characteristics: a) particles in the orientation field; b) particles in the measuring field.

The studies of the characteristics of the dust of magnetizing roasting of the ore used dust taken from the collector during preventive stops of kilns and dust made from the scrubber in the form of a suspension in water. The suspension was precipitated and dried at a temperature of 105-110 °C to constant weight.

In Fig. 3 and 4 show the disperse and magnetic properties of the dust from kilns taken from the collector, and in Fig. 5 and 6 taken from the scrubber.

Fig. 3. The disperse and magnetic properties of the not magnetized dust from the collector generated by magnetizing roasting of the ore

Fig. 4. The disperse and magnetic properties of the magnetized dust from the collector generated by magnetizing roasting of the ore

A comparative analysis of the results shows that the dust taken from the collector has a more significant number of large fractions than the dust made from the scrubber. In the collector, predominantly large particles settle, which are more challenging to carry through the air stream. The dust taken from the collector has an initial magnetization.

Fig. 5. The disperse and magnetic properties of the not magnetized dust from the scrubber generated by magnetizing roasting of the ore

Fig. 6. The disperse and magnetic properties of the not magnetized dust from the scrubber generated by magnetizing roasting of the ore

The dust sampled from the scrubber has no initial magnetization. Because in the dust of the scrubber, there is a higher number of small particles, the temperature of which in the furnace passes through the Curie point. In this case, demagnetization occurs. Large particles have higher thermal inertia and, therefore, do not always have time to demagnetize. Small particles have a large specific surface, therefore, in the process of magnetizing firing, they are better restored, and their magnetic properties increase more. This feature explains the sizeable final magnetization of dust taken from the scrubber.

The studies of the characteristics of the dust generated during transportation of concentrate used the dust sampling from the cyclone hopper. In Fig. 7 and 8 show the results of studies of the dispersed and magnetic properties of dust.

Fig. 7. The disperse and magnetic properties of the not magnetized dust of concentrate

Fig. 8. The disperse and magnetic properties of the magnetized dust of concentrate

An analysis of the results shows that a significant proportion of the magnetic substance in the dust of concentrate is 97% versus 42% for the dust from the kiln. This circumstance, as well as the fact that the enriching of the ore is by strong magnetic fields, determines the high initial and final magnetization of this type of dust.

The studies of the characteristics of the dust generated during the firing of pellets used the dust sampling from the outer hatches of the cyclone hopper. Dust formed because of the impacts of the pellets against each other and the wall of the kiln. Therefore, a higher number of finely dispersed particles with significant magnetization and initial magnetization appear. The research results are shown in Fig. 9 and 10. An analysis of the results shows that a high average dust magnetization (4.5 kA/m) created by large fractions (23.4-54.6 μm). However, particles less than 15.6 μm in size have the greatest magnetization (up to 30 kA/m). A difference in the magnetization of the particles of the 2.8 μm fraction in the magnetized and non-magnetized state noted this is because of the temperature transition of these particles during firing through the Curie point.

Fig. 9. The disperse and magnetic properties of the not magnetized dust generated during the firing of pellets

The studies of the characteristics of the dust of the sinter machine used the dust sampling from the cyclone hopper, as well as from electrostatic precipitators during the preventive stop of the sinter machine. In Fig. 11 – 14 show dust research results.

A comparison of the results shows that the dust selected from the III zone of electrostatic precipitators has the smallest average size and the largest residual magnetization. From cyclone to zone III, the fraction of magnetized particles, as well as their remanent magnetization, increases in each dust fraction. From the

cyclone to III in each zone increases the proportion of magnetized particles fractions of dust and their remanence. This feature explained by the fact that when moving at a higher speed in an inhomogeneous electric field, the particles experience the action of a magnetic field. Because of this, the magnetization of dust occurs.

Fig. 14. The disperse and magnetic properties of the dust of the sintering machine from electrostatic precipitator zone II

In Fig. 15 – 16 shown the comparative characteristics of all investigated dust. It is known that when mixing solids, the uniformity of the mixture increases with a decrease in the size of its constituent particles. Most of the studied dust consists of particles with a size of 31.2 – 62.0 μm (Fig. 3). Only for agglomeration dust from the III zone of the electrostatic precipitator, the bulk of the particles have a size of 12.6–31.2 μm . When mixed with cement, this dust allows getting the most uniform distribution of particles in the binder.

Researches show that after magnetization in the dust, the proportion of largess particles increases due to smaller ones. The study of this phenomenon showed that this is due to the aggregation of magnetized particles.

Fig. 15. Fractional composition of the dust. Dust numbers correspond to table 5.

Fig. 16. The average value of the magnetization of dust by fractions, kA/m. Dust numbers correspond to table 5.

The magnetic field strength decreases in proportion to the distance from the source. Calculations show that an

increase in the size of dust particles at a constant concentration in the binder increases the distance between the dust particles, the sources of the magnetic field. Increases of the distance create an uneven magnetic field inside the binder and, accordingly, an inhomogeneous activation effect. On the contrary, a decrease in the size of dust particles leads to a decrease in the distance between the magnetic field sources and an increase in the quality of the activation effect. The majority of particles with magnetic properties in most dust have a size of 31.2 – 62.0 μm .

The most significant part of the magnetic particles in the dust of the sintering machine has a size of 12.6 – 31.2 μm , and the fraction 1.4 – 12.6 μm from the III zone of the electrostatic precipitator accounts for more than 13% of all magnetic particles. This fact allows us to conclude that using the dust of the sintering machine from zone III of the electrostatic precipitator as an activating additive can be achieved the highest uniformity of magnetic fields in cement.

The methodology used to study the properties of dust used in this work makes it possible to determine the contribution of each fraction to the creation of a magnetization. Studies have shown that the magnetization of dust particles increases with decreasing particle size. The dust is polymineral and contains in its composition both components with and without magnetic properties. During particle fragmentation, the destruction occurs primarily along the cleavage planes of grains having differences in magnetic properties. As a result, either particle having high magnetic characteristics or not having them at all formed.

It is characteristic of the studied dust that with a decrease in the size of the fractions, the fraction of dust particles with magnetic properties decrease. However, the large magnetization of fine dust is the reason that a decrease in the proportion of magnetic particles does not correspond to a decrease in magnetization. For example, in agglomeration dust from the III zone of electrostatic precipitators, the proportion of particles with a size of 1.4 – 12.6 μm having magnetic properties is 5.2% of the total mass of dust, and their contribution to the total magnetization is 15.3%.

In most dust, particles of 12.6 – 62.0 μm is made the main contribution to the creation of magnetization (Fig. 4).

Dust of the sintering machine from electrostatic precipitator zone III creates the bulk of the magnetization by particles of 1.4 – 31.2 μm in size, which is a prerequisite for obtaining a high activation effect.

The averaged values of the magnetic and dispersed properties of the dust required for further studies shown in Fig. 17 and 18.

If the mean diameter of dust particles, their mass and mass fraction in the mixture is known, assuming that the particles located in the mix at the same distance, we can calculate the average length, r_{mean} between dust particles in the mixture with cement.

In total, were studied 12 dust with various combinations of magnetic and dispersed characteristics. Since other characteristics of dust differ little from each other, the obtained results allow us to conduct studies to

identify the general laws of the influence of various dust on the activation of a binder.

Fig. 17. The mean diameter of different types of dust.

Fig. 18. The mean magnetization of different types of dust.

The average diameter of the largest of the studied dust is 2.5 times larger than that of the smallest. The minimum and maximum values of the average magnetization of different dust differ by more than 40 times.

Processing of the obtained data has shown the relationship between the activity of binders and the magnetic and dispersed characteristics of the introduced additives. In studying were investigated the strength characteristics of cement-sand mortars made from binders containing 98% of blast furnace cement and 2% of one of the dust. Mixing cement with the additive was carried out in a ball mill for 8 minutes. Further tests were carried out by DSTU EN 196-1:2007. In table 6 and Fig. 19 – 20 show the test results.

Processing of the results showed that the increase in strength correlates with the average distance between particles and the magnetization of dust. Dependencies are:

$$R_m = 5,376 + 0,0012 \left(\frac{I_{\text{mean}}}{r_{\text{mean}}} \right) \quad (1)$$

$$R_c = 37,84 + 0,028 \left(\frac{I_{\text{mean}}}{r_{\text{mean}}} \right) \quad (2)$$

Correlation coefficients for (1) – $K_{\text{cor}} = 0.913$ with a standard error of 0.07, for (2) – $K_{\text{cor}} = 0.911$ with a standard error of 1.7.

Reducing the size of dust particles affects the activation effect in two ways: firstly, the uniformity of mixing of particles increases, which improves the uniformity of magnetic fields induced by dust, and

secondly, with decreasing particle size, their magnetization increases, which also increases the activity of binders.

Table 6. The dependence of the characteristics of cement-sand mortars on the properties of the introduced iron dust.

Type of input dust	The mean distance between particles in the mixture $r_{mean}, \mu m$	$\frac{I_{mean}}{r_{mean}}$	R_m, MPa	R_c, MPa
No additives			5.26	33.45
Not magnetized from the collector	14.8	25.5	5.42	37.36
Magnetized from the collector	15.4	31.0	5.46	38.39
Magnetized from the scrubber	11.1	163.5	5.52	42.22
Not magnetized dust of concentrate	20.2	11.9	5.31	39.2
Magnetized dust of concentrate	13.8	101.4	5.54	43.67
Not magnetized dust of the sintering machine	9.4	221.8	5.52	42.22
Magnetized dust of the sintering machine	11.6	238.0	5.75	46.92
From cyclone	7.8	7.4	5.37	36.72
From electrostatic precipitator zone II	10.5	13.7	5.43	37.95
From electrostatic precipitator zone III	6.1	366.9	5.81	47.34

Fig. 19. Effect of dust characteristics on cement bending strength.

Fig. 20. Effect of dust characteristics on cement compressive strength

It follows that the most significant activation effect achieved by introducing iron-containing magnetized dusty substances into the binder, in which the ratio I_{mean}/r_{mean} is of the highest importance. Among those considered, this is the dust of the sintering machine taken from electrostatic precipitator zone III. Its activation effect, along with magnetized dust from the kiln, is 41%. However, unlike the latter, dust from the III zone of the electrostatic precipitator does not need magnetization.

5 Conclusions

The studies show that the magnetic characteristics determined by the origin and method of dust collection. Studies revealed that with decreasing dust particle size, their magnetization increases. After additional magnetization, the fractional composition of dust changes due to the aggregation of small parts into large ones.

The studied dust has 12 different combinations of magnetic and dispersed characteristics, which is enough to identify the patterns of the influence of each of the factors on the activity of binders.

In studies was established that from the studied dust, the highest uniformity of magnetic fields in the binder allows getting dust from the III zone of the sinter machine electrostatic precipitators.

The investigation established that the introduction of pre-magnetized ferromagnetic dust into the composition of blast furnace cement has an activating effect on the process of binder hydration.

Studies proved that the degree of influence of the additive on the binder activity depends on the distance between the dust particles and the magnetic field strength.

In the future, it is necessary to study the processes of structure formation under the influence of a ferromagnetic additive and their influence on the strength and deformation characteristics of mortar and concrete.

Comparative analysis of strength and deformation of reinforced concrete and steel fiber concrete slabs

Mykola Surianinov*, Stepan Neutov, and Iryna Korneieva

Odesa State Academy of Civil Engineering and Architecture, Odesa, 65029, Ukraine

Abstract. The results of experimental studies of the steel fiber influence on the bearing capacity, deformability and crack resistance of reinforced concrete multi-hollow plates are given. We investigated a serial floor slab and a similar one, but with the addition of steel fiber. Both plates are factory-made. For testing, the testing apparatus was designed and manufactured that made it possible to study full-size floor slabs in laboratory conditions. The tests were carried out according to a single-span scheme with the replacing equivalent load. The loading was carried out by applying two concentrated strip vertical loads along the plate width. The load was applied in steps of $(0.04 \div 0.05)$ from the breaking load. Each stage ended with exposure lasting up to 10 minutes with fixing all the necessary parameters. Deformations were measured using dial gauges. From the moment the first crack appeared in the stretched zone of concrete, the process of crack formation and opening was monitored. At each level, using the Brunell tube, the width of their opening and height were measured. The moment of cracking in both slabs began at the same relative strain. It has been established that the bearing capacity and crack resistance of a slab of combined reinforcement using steel fiber are respectively 50 and 44% higher than that of a similar reinforced concrete slab. The maximum deflection of the slab of combined reinforcement is 37.5% lower than that of conventional reinforced concrete. The destruction of both slabs occurred under loads, when the relative deformations in the compressed zone of concrete reached 0.80×10^{-3} and 1.10×10^{-3} for reinforced concrete and steel-fiber concrete slabs, respectively, the difference is 37.5%.

1 Introduction

Hollow core slabs are usually used as slabs between floors in the construction of buildings and structures. Of various shapes and sizes, with different bearing patterns, they are all widely used in construction. Their production accounts for a significant mass part of reinforced concrete of the total material consumption during the construction of the facility. This type of product can be called universal, because its use is not limited to the type of structure. The main distinguishing feature of such floor slabs is the presence of voids located along the slab. These voids almost always have a circular cross section. Also, characteristic is the manufacture of recessed grooves along the side faces. Such plates are pre-stressed and non-stressed by pouring into molds and subsequent vibration compaction with final heat treatment.

The improvement of such demanded reinforced concrete structures, the increase in their bearing capacity, crack resistance and durability is an actual problem.

2 Recent researches analysis

It is known that the use of steel fiber leads to an increase in the physicomachanical characteristics of concrete, namely, strength, deformability, crack resistance, water

permeability, impact strength, frost resistance, etc. [1-3].

Most of these characteristics are usually determined in the laboratory. In this case, the main objects of research are samples in the form of cubes or prisms, and less often – models in the form of beams or slabs of reduced size.

Over the past five years, the authors have carried out large-scale studies to determine the effect of steel fiber on the strength and deformation properties of fiber concrete [4, 5]. It was found that the strength and crack resistance of steel fiber concrete, higher than that of ordinary concrete, on average, by 40 and 30%, respectively. Creep – on the contrary, is (20-22)% lower. The long-term strength of steel fiber-reinforced concrete beams that have been exposed to operational loads for more than 400 days is on average 37% higher than that of similar beams made of ordinary concrete. All these results were obtained, again, in laboratory conditions, and, as it is known, they are far from always confirmed by the operation of real structures.

Studies to expand the scope of steel fiber concrete are carried out by many authors [6-8]. So, in [9], the use of fiber-reinforced concrete slabs is considered, which are more economically and technically profitable compared to conventional reinforced concrete slabs when installing floors. The author substantiates this by an increase in impact strength and ductility, higher crack resistance and bearing capacity. An interesting comparison of the

* Corresponding author: sng@ogasa.org.ua

properties of concrete slabs with two types of fiber fibers and in the absence of fiber reinforcement was presented in [10]. Four specimens contained steel and polypropylene fibers added in a volume ratio of 0.5% and 1.0%. The slabs had dimensions of $820 \times 820 \times 80$ mm and were supported by four rollers along the edges that control the displacement. The concentrated load is applied in the center of the plate. The results of experimental studies were compared with theoretical predictions. Based on the processing of the data obtained, it was concluded that 1% of steel fibers by volume has the best effect on the operation of the slabs. This conclusion coincides with our results regarding the effectiveness of fiber reinforcement.

A. Blanco [11] believes that combining fibers with traditional reinforcement can be a very interesting design decision to create more durable and economical designs. His work is devoted to the analysis of the bearing capacity and ultimate state of slabs. For this purpose, eighteen concrete slabs ($3 \times 1 \times 0.2$ m) with different reinforcement, fiber types (steel and plastic) and their volumetric content (0.25 and 0.50%) were investigated. These slabs were tested for bending with data monitoring at four points.

The works of other authors can be noted [13-14], but nevertheless, the influence of steel fiber on the work of flexible concrete elements has not been fully studied, and many aspects of practical interest remain.

3 The purpose of work

The aim of this work is an experimental study of the influence of steel fiber on the bearing capacity, deformability and crack resistance of serial reinforced concrete multi-hollow slabs manufactured in the factory.

4 Materials and methods

The object of the study are floor slabs PK 30.12-8, manufactured in the factory by the enterprise Velikodolinsky ZhBK Plant, LLC in accordance with regulatory documents [15, 16] and working drawings of the 1.141-1 series [17], using conventional technology and with the addition of steel fiber with curved ends.

For testing, a testing apparatus was designed and manufactured that made it possible to study full-sized floor slabs in laboratory conditions (Fig. 1). In order to comply with safety regulations and prevent brittle collapse of reinforced concrete slabs during the test under load, steel pipes were freely threaded into the extreme voids, which did not impede the deformation of the structure. This made it possible to timely detect the appearance of cracks, safely measure their parameters and draw on the underside of the slab.

Fig. 1. Testing apparatus.

To determine the strength properties of concrete, at the factory, samples of cubes with a rib size of 10 cm were made from the same mixture as the slab, which were tested for compression in laboratory conditions. The obtained value of cubic strength showed that concrete corresponds to grade C16/20. Determination of concrete strength during short-term loading was carried out in accordance with the requirements of current standards [18, 19].

The tests were carried out according to a single-span design with a substitute equivalent load (Fig. 2). The loading was carried out by applying two concentrated strip vertical loads along the slab width.

5 Research results

Two multi-hollow floor slabs were tested, one is ordinary reinforced concrete (PK series 30.12-8), and the second is similar, but with the addition of 1% steel fiber. Slabs have dimensions in the plan of 1190×2980 and a height of 220 mm (Fig. 3), concrete consumption 0.43 m^3 .

During the tests, the load applied to the element and the corresponding deformations were recorded; tests were carried out in accordance with [20].

The load was applied in steps of $(0.04 \div 0.05)$ from the breaking load. Each stage ended with exposure lasting up

to 10 minutes with fixing all the necessary parameters. Deformations were measured using dial gauges with a division price of 0.001 mm and a base of 25 cm. Five gauges (3, 4, 5, 6, and 7) were installed on the upper surfaces of the slabs, in the central part (Fig. 3). Gauges 1, 2 and 8, 9 were fixed to the side surfaces (faces) of the plates. The first two gauges were located in the middle of the span in the zone of clean bending, and a pair of indicators 8, 9 in the zone of load transfer (Fig. 3). The first and ninth gauges are in the stretched zone of concrete, 2 and 8 are in the compressed.

From the results shown in Fig. 4 and 5, it follows that the readings of all 5 gauges located on the upper surfaces

of the slabs from the beginning of loading and up to failure change equally synchronously and almost by the same value. The latter indicates that the loading of reinforced concrete slabs using a two-level cross-beam system ensures uniform loading of its upper surface.

From the moment the first crack appeared in the stretched zone of concrete, the process of crack formation and opening was monitored. At each level, using the Brunell tube, the width of their opening and height were measured.

Fig. 2. Loading concept.

Fig. 3. Indicator layout.

Fig. 4 shows the nature of the deformations obtained in the process of loading a reinforced concrete floor slab. From the results shown in the figure, it can be seen that three sections can be distinguished on the deformation curves.

I section. Up to a load level of 44.41 kN, corresponding to the beginning of crack formation, a linear relationship is observed for all concrete fibers. The values of relative deformations in the compressed and stretched zones are almost the same ($\epsilon = 0.1 \times 10^{-3}$).

II section. At VIII-X loading steps, when the load varies in the range from 44.41 kN to 59.21 kN, a sharp change in the strain growth rate occurs (the angle of

inclination of the curves changes significantly). Deformations in the compressed and stretched zones of concrete increase almost 3 times. Such a significant increase in deformation is explained by the avalanche-like process of cracking (12 cracks with an opening width of up to 0.005 mm).

In section III, with a load of more than 59.21 kN, the relative deformations in the compressed zone of concrete again change almost linearly up to the breaking load (108.55 kN) and amount to 0.75×10^{-3} . In the stretched zone of concrete, the strain growth rate is significantly higher. Deformations from 0.2×10^{-3} increased to 1.4×10^{-3} , 2 times higher than the deformation of the compressed

zone of concrete. This is explained by the fact that, at this stage of loading, along with the formation of new cracks, the process of opening previously formed cracks is

intensified. The width of their disclosure increases 3-4 times.

Fig. 4. Deformation of a hollow-core reinforced concrete slab according to indicators.

Figure 5 shows the deformation of concrete fibers in a steel-fiber concrete slab.

The nature of the curves shown in Fig. 5 is similar to the nature of the strain curves of concrete fibers in a conventional reinforced concrete slab (Fig. 4). Namely, a linear relationship is observed up to the load level corresponding to the onset of crack formation (64.14 kN). Relative deformations corresponding to the indicated load do not exceed the value of 0.1×10^{-3} .

The latter indicates that the cracking moment in both slabs begins at the same relative strain equal to 0.1×10^{-3} .

At the second stage, in the range of load changes from 64.14 kN to 78.95 kN, the relative deformations in the compressed zone of concrete increase to 0.2×10^{-3} , which is two times lower than in a slab of ordinary reinforced concrete. This is explained by the fact that 12 cracks

formed in an ordinary slab at this stage, and in a slab of steel-fiber-reinforced concrete – 7. Moreover, not only the number of cracks, but also the width of their opening is 1.7 times smaller.

In the third section, at loads greater than 78.95 kN, the relative deformations in the compressed zone of concrete again change linearly up to a breaking load of 162.83 kN.

Comparing the results shown in Fig. 4 and 5, it is easy to verify that the destruction of the investigated plates occurred when the relative deformations in the compressed zone of concrete reached 0.80×10^{-3} and 1.10×10^{-3} for reinforced concrete and steel-fiber concrete plates, respectively; the difference is 37.5%.

In a reinforced concrete slab, this deformation occurs at a load of 108.55 kN, and in a steel-fiber concrete slab at 162.83 kN; these values differ by 50%.

Fig. 5. Deformation of a hollow-core steel fiber concrete slab according to indicators.

Figure 6 shows the nature of the changes in the deflection of a reinforced concrete slab during its loading. Deflections were measured using the Maximov deflections with a division value of 0.01 mm. The results presented in Fig. 6 are identical to the results shown in Fig. 4, in the sense that the previously described stages of structural deformation are clearly traced on the curves.

Stage I to the load level of 44.41 kN (41% of the destructive) – linear. The maximum deflection at the end of the stage is 1.7 mm, i.e. 7% of its maximum value at the destruction moment.

At stage II, the linearity is substantially violated, and by the end of the stage, the deflections increase to 5.5 mm, i.e. more than 3 times with an increase in load of only 10%. This is also explained by the fact that 12 cracks formed in the plate at this stage.

At stage III, the load compared to the first two stages doubled, and the deflections increased five times to a value of 2.5 cm.

In Figure 7 shows the nature of the change in deflections in a steel-fiber concrete slab during its loading. In this figure, as in the previous ones, 3 sections can be distinguished. The first one is linear up to the load level corresponding to the moment of crack formation (64.14 kN).

At the second section, in the load interval from 64.14 kN to 123.35 kN, linearity is broken, because 19 cracks with an opening width not exceeding 0.005 mm are formed.

In the third section, the load varies from 123.35 kN to 162.83 kN. The process of formation of new cracks is significantly slowed down (5 new cracks), and in parallel with it, the process of intensive opening of existing cracks begins. The width of the opening of five cracks increased 10 times (0.05 mm).

Figure 8 shows for comparison the deflections in reinforced concrete and steel fiber concrete slabs. From the presented results it is seen that the maximum deflection in a steel-fiber concrete slab is 37.5% less than in a similar reinforced concrete slab.

This is explained by the fact that at the time of fracture in a conventional reinforced concrete slab there were 8 through cracks with an opening width of up to 0.1 mm, while in a steel fiber reinforced concrete slab there were only 4 with an opening width not exceeding 0.06 mm. In addition, the total magnitude of the opening of all cracks in an ordinary slab is 1.57 mm, and in steel-fiber concrete – only 0.52 mm, i.e., almost 3 times less.

Fig. 6. Deflection of a reinforced concrete slab in the center of the span according to the readings of two deflection meters.

Fig. 7. Deflection of a steel fiber concrete slab in the center of the span according to the readings of two deflection meters.

Fig. 8. Deflections of hollow-core slabs in the center of the span 1 – steel fiber concrete slab, 2 – reinforced concrete slab.

Along with indicators, strain gauges with a strain measurement base of 50 mm were glued on the upper and lateral surfaces of reinforced concrete and steel fiber reinforced concrete slabs (Fig. 9). The results presented in Fig. 10, indicate that two completely unrelated strain measurement systems show very close values (the difference does not exceed 5%).

Fig. 9. The location of the strain gauges under the indicator.

Fig. 10. The deformation of the longitudinal fibers of the upper side of the plate according to the indications of the indicator and strain gauge: 1 – according to the indications of the indicator, 2 – according to the indications of the strain gauge.

6 Conclusions

An analysis of the experimental studies showed that the main parameters that determine the physicomaterial characteristics of concrete and fiber-reinforced concrete, namely, bearing capacity, deformability and crack resistance, are interconnected throughout all stages of loading.

1. The bearing capacity and crack resistance of a slab of combined reinforcement using steel fiber are respectively

50 and 44% higher than that of a similar reinforced concrete slab.

2. The maximum deflection of the slab of combined reinforcement is 37.5% lower than that of ordinary reinforced concrete.

3. The destruction of both slabs occurred under loads, when the relative deformations in the compressed zone of concrete reached $0.80 \cdot 10^{-3}$ and $1.10 \cdot 10^{-3}$ for reinforced concrete and steel-fiber concrete slabs, respectively, the difference is 37.5%.

Stability of orthotropic plates

Mykola Surianinov^{1,*}, Dina Lazarieva¹, and Iryna Kurhan²

¹Odesa State Academy of Civil Engineering and Architecture, Odesa, 65029, Ukraine

²Odesa National Polytechnical University, Odesa, 65044, Ukraine

Abstract. The solution to the problem of the stability of a rectangular orthotropic plate is described by the numerical-analytical method of boundary elements. As is known, the basis of this method is the analytical construction of the fundamental system of solutions and Green's functions for the differential equation (or their system) for the problem under consideration. To account for certain boundary conditions, or contact conditions between the individual elements of the system, a small system of linear algebraic equations is compiled, which is then solved numerically. It is shown that four combinations of the roots of the characteristic equation corresponding to the differential equation of the problem are possible, which leads to the need to determine sixty-four analytical expressions of fundamental functions. The matrix of fundamental functions, which is the basis of the transcendental stability equation, is very sparse, which significantly improves the stability of numerical operations and ensures high accuracy of the results. An analysis of the numerical results obtained by the author's method shows very good convergence with the results of finite element analysis. For both variants of the boundary conditions, the discrepancy for the corresponding critical loads is almost the same, and increases slightly with increasing critical load. Moreover, this discrepancy does not exceed one percent. It is noted that under both variants of the boundary conditions, the critical loads calculated by the boundary element method are less than in the finite element calculations. The obtained transcendental stability equation allows to determine critical forces both by the static method and by the dynamic one. From this equation it is possible to obtain a spectrum of critical forces for a fixed number of half-waves in the direction of one of the coordinate axes. The proposed approach allows us to obtain a solution to the stability problem of an orthotropic plate under any homogeneous and inhomogeneous boundary conditions.

1 Introduction

The development level of production at the present stage is characterized by the widespread introduction of new technologies for the manufacture of high-strength materials with orthotropic (orthogonally anisotropic) properties.

Such materials include fiberglass; composite materials reinforced with sequentially alternating layers of fibers in two mutually perpendicular directions; glued wood plates; sheet rolled metals, in which anisotropy begins to appear upon transition to the plastic stage of work, etc.

The widespread use of materials with anisotropic properties has given rise to large-scale studies in the field of mechanics of anisotropic structures and, in the first place, plates.

In many industries, designs in the form of plates made of orthotropic materials with three planes of symmetry of elastic properties are widely used. Under certain conditions, the operation of such plates is accompanied by the appearance of compressive stresses

in the median plane, which can lead to a loss of stability and bearing capacity of the plate.

Determining the critical load on a plate presents serious mathematical difficulties not only for orthotropic, but also for isotropic plates. In well-known monographs and reference books, only the stability problem of a rectangular plate with a hinged support along the contour is solved [1-4].

2 Latest researches analysis

The stability problem of an isotropic rectangular plate loaded on two opposite edges by forces distributed according to a linear law was first solved by I. G. Bubnov and S. P. Timoshenko [5]. For an orthotropic plate, this problem was solved by S. G. Lehnitsky [6]. All these classical solutions are obtained for the case of the edges simple support of the plate in the form of double trigonometric rows.

From later works, we note I. E. Harik papers [7, 8], the first of which sets out a numerical-analytical method for the analysis of orthotropic rectangular plates subject to uniform, linearly changing and piecewise-continuous plane loads; the decision procedure is based on the

* Corresponding author: sng@ogasa.org.ua

classical method of variables separation. And the second one proposes an analytical method for solving the problem of elastic bending of orthotropic rectangular plates under different boundary conditions. A generalization of all the results obtained in this direction was made by F. Bloom and D. Coffin in an interesting Handbook [9], which is, in our opinion, the most comprehensive review of theoretical methods for calculating the stability of thin plates.

There are very few contemporary works devoted to the stability of anisotropic plates. We note the paper [10], where the stability problem of an anisotropic plate is solved (but again with a hinged support along the contour) and the work [11], where the stability problem is solved for pure bending of an orthotropic plate, in which two opposite edges are free and two other edges articulated. The finite difference method was used here. The works of foreign authors are based primarily on the use of numerical methods, and, most often, the finite element method and its modifications are encountered. The paper [12] considers the analysis of vibrations and stability of thick orthotropic plates using finite elements based on the Trefftz hybrid formula. The Trefftz type finite element method (TFEM) is used by C. Young [13] to solve some potential problems in orthotropic environment. The method of boundary elements in classical form was used in [14]. Here, fundamental solutions are obtained for orthotropic thick plates with allowance for lateral shear strain. Boundary integral equations are formulated that are adapted to arbitrary boundary conditions. Examples of numerical implementation are given.

3 Research aim

The aim of research is an experimental study of the influence of steel fiber on the bearing capacity, deformability and crack resistance of serial reinforced concrete multi-hollow slabs manufactured in the factory.

4 Materials and methods

Problems of this kind can be solved by numerical methods, such as the finite element method, the finite difference method, the R-function method, etc., but it is advisable to verify the results by any analytical method. It seems that such is the NA BEM. As is known [15], the basis of this method is the analytical construction of the fundamental system of solutions and Green's functions for the differential equation (or their system) for the problem under consideration. To account for certain boundary conditions, or contact conditions between the individual elements of the system, a small system of linear algebraic equations is compiled, which is then solved numerically. In this case, no restrictions are imposed either on the boundary conditions or on the nature of the external load. Note that the method is strictly mathematically justified, since it uses fundamental solutions of differential equations, therefore, taking into account the initially accepted

hypotheses, it allows to obtain exact values of the desired quantities of the problem.

5 Research results

The differential stability equation of an orthotropic plate within the framework of the Kirchhoff-Love hypothesis (Fig. 1) can be written as

$$\begin{aligned} D_1 \frac{\partial^4 W(x, y)}{\partial x^4} + 2D_3 \frac{\partial^4 W(x, y)}{\partial x^2 \partial y^2} + D_2 \frac{\partial^4 W(x, y)}{\partial y^4} + \\ + N_x(y) \frac{\partial^2 W(x, y)}{\partial x^2} + 2N_{xy} \frac{\partial^2 W(x, y)}{\partial x \partial y} + \\ + N_y(x) \frac{\partial^2 W(x, y)}{\partial y^2} = q(x, y), \end{aligned} \quad (1)$$

where stiffnesses are defined by formulas

$$\begin{aligned} D_1 = \frac{E_x h^3}{12(1 - \mu_{xy} \mu_{yx})}; \quad D_2 = \frac{E_y h^3}{12(1 - \mu_{xy} \mu_{yx})}; \\ D_3 = D_1 \mu_{xy} + 2D_k = D_2 \mu_{yx} + 2D_k; \quad D_k = \frac{Gh^3}{12}. \end{aligned}$$

Here E_x, E_y – moduli of elasticity in the axis directions; G – shear modulus; h – plate thickness; μ_{xy}, μ_{yx} – Poisson's ratio; $W(x, y)$ – deflection amplitude value; $N_x(y); N_{xy}; N_y(x)$ – forces in the middle plane; $q(x, y)$ – transverse load amplitude.

Fig. 1. Plate loads.

The stability equation (1) is of the fourth order and is a partial differential equation. Function $W(x, y)$, which is the solution of this equation, depends on two variables. The transition from a two-dimensional problem to a one-dimensional one, as required by the algorithm of the NA BEM, can be accomplished by applying the Kantorovich-Vlasov variational method.

Let's expand the deflection $W(x, y)$ into functional series:

$$\begin{aligned} W(x, y) = W_1(y)X_1(x) + W_2(y)X_2(x) + \dots \\ \dots + W_n(y)X_n(x). \end{aligned} \quad (2)$$

Functions $X_i(x)$ it is necessary to choose such that they most accurately describe the shape of the curved

surface of the plate in the direction of the axis ox . Deflection curves for a beam that has the same abutment conditions as the plate in the direction of the axis ox meet his requirement. To select the lateral deflection distribution function $X_i(x)$ there are known two methods – static and dynamic [15]. When using the static method, the deflection of the beam is determined by the static load. This load should be such that symmetric and skew-symmetric forms of the deflection curve alternate alternately. Functions $X_i(x)$ are represented in the form of power polynomials that are easy to differentiate, integrate and calculate without the use of complex programs. When using the dynamic method, beam deflections are represented by forms of its own vibrations. In a static way, you need to build functions $X_i(x)$ depending on the load and reactions of the beam. In the dynamic method, it is enough to change only the values of the natural frequencies, which is very convenient.

We will keep in (2) one member of the series, which, as shown in [15], is sufficient to obtain a result of acceptable accuracy, i.e.

$$W(x, y) = W(y)X(x). \quad (3)$$

Let's substitute (3) into (1):

$$D_1 X^{IV} W + 2D_3 X'' W'' + D_2 X W^{IV} + N_x(y) W X'' + 2N_{xy} W' X' + N_y(x) W'' X = q(x, y). \quad (4)$$

Multiply both sides of (4) by X and integrate within $[0; l_1]$, where l_1 – plate dimension in axis x direction (Fig. 1).

$$\begin{aligned} D_1 W \int_0^{l_1} X^{IV} X dx + 2D_3 W'' \int_0^{l_1} X'' X dx + D_2 W^{IV} \int_0^{l_1} X^2 dx + \\ + N_x(y) \int_0^{l_1} X'' X dx + 2W' \int_0^{l_1} N_{xy} X' X dx + W'' \int_0^{l_1} N_y(x) X^2 dx = \\ = \int_0^{l_1} q(x, y) X dx. \end{aligned}$$

We introduce the notation:

$$\begin{aligned} D_2 \int_0^{l_1} X^2 dx = A; \quad \int_0^{l_1} [2D_3 X'' + N_y(x)] X dx = B; \\ \int_0^{l_1} 2N_{xy} X' X dx = K; \quad \int_0^{l_1} [D_1 X^{IV} + N_x(y)] X dx = C, \end{aligned}$$

then

$$AW^{IV} + BW'' + KW' + CW = q(y), \quad (5)$$

where

$$q(y) = \int_0^{l_1} q(x, y) X dx.$$

Coefficients A, B, K, C can be calculated in any mathematical program with almost any accuracy.

From the introduced notation it follows that $N_y(x)$ can be any function of x , while $N_x(y)$ and $N_{xy}(x)$ should be piecewise constant functions of y , since otherwise, equation (5) will be a differential equation with variable coefficients.

Divide all the terms of equation (5) by A :

$$W^{IV} + 2r^2 W'' + f^3 W' + s^4 W = \frac{1}{A} q(y), \quad (6)$$

where

$$r^2 = \frac{B}{2A}; \quad f^3 = \frac{K}{A}; \quad s^4 = \frac{C}{A}$$

Equation (6) with initial conditions $W(0), \theta(0), M(0), Q(0)$ forms the Cauchy's problem:

$$\begin{aligned} \begin{vmatrix} W(y) \\ \theta(y) \\ M(y) \\ Q(y) \end{vmatrix} = \begin{vmatrix} A_{11} & A_{12} & -A_{13} & -A_{14} \\ A_{21} & A_{22} & -A_{23} & -A_{13} \\ -A_{31} & -A_{32} & A_{22} & A_{12} \\ -A_{41} & -A_{31} & A_{21} & A_{11} \end{vmatrix} \begin{vmatrix} W(0) \\ \theta(0) \\ M(0) \\ Q(0) \end{vmatrix} + \\ + \int_0^y \begin{vmatrix} A_{14}(y-\xi) \\ A_{13}(y-\xi) \\ -A_{12}(y-\xi) \\ -A_{11}(y-\xi) \end{vmatrix} q(\xi) d\xi. \end{aligned}$$

The solution of the Cauchy problem allows us to determine the fundamental functions, the form of which depends on the roots of the characteristic equation

$$t^4 + 2r^2 t^2 + f^3 t + s^4 = 0 \quad (7)$$

Consider the practically important case when $N_{xy} = 0$. Moreover, in equation (7) will be $f = 0$, and the roots of the characteristic equation are calculated by the formulas

$$t_{1-4} = \pm \sqrt{r^2 \pm \sqrt{r^4 - s^4}}$$

The form of fundamental functions is determined by the relation between r and s , which depends on the fixing conditions of the longitudinal edges of the orthotropic plate. Four options are possible for this ratio:

1. $|s| > |r|$ – complex roots: $t_{1-4} = \pm \alpha \pm i\beta$, where $\alpha = \sqrt{\frac{s^2 - r^2}{2}}$; $\beta = \sqrt{\frac{s^2 + r^2}{2}}$.
2. $s^4 < 0, r^2 \neq 0$ – real and imaginary roots: $t_{1-2} = \pm \alpha; t_{3-4} = \pm i\beta$.
3. $s^4 > 0, |s| < |r|, r^2 > 0$ – imaginary roots: $t_{1-2} = \pm i\alpha; t_{3-4} = \pm i\beta$.
4. $s^4 > 0, r^4 - s^4 > 0, r^2 < 0$ – real and different roots: $t_{1-2} = \pm \alpha; t_{3-4} = \pm \beta$.

After determining the fundamental functions, one can compose a transcendental equation of stability of an

orthotropic plate, which in the general case will have the form

$$|A_*(N_x, N_y, N_{xy}) = 0| \quad (8)$$

where A_* – a square matrix of values of fundamental orthonormal functions with compensating elements describing the topology of the system.

Option 1

Option 2

Fig. 2. Two options of boundary conditions.

Initial data for calculation:

Elasticity moduli – $E_x = 5 \cdot 10^3$ MPa, $E_y = 200 \cdot 10^3$ MPa, $E_x = 5 \cdot 10^3$ MPa; shear moduli – $G_{xy} = 12,5 \cdot 10^3$ MPa, $G_{yx} = 25 \cdot 10^3$ MPa, $G_{xz} = 50 \cdot 10^3$ MPa; Poisson's ratios – $\mu_{xz} = 0,1$, $\mu_{yz} = 0,15$, $\mu_{xy} = 0,0075$.

The numerical implementation of the NA BEM algorithm is performed in the Excel. The results are shown in table 1.

Table 1. Critical loads, calculated by two methods.

Load, kN/m	Option 1			Option 2		
	BEM	ANSYS	%	BEM	ANSYS	%
σ_1	11395	11436	0,36	12320	12372	0,42
σ_2	11758	11808	0,42	35953	36101	0,41
σ_3	14989	14958	0,46	41669	41872	0,48
σ_4	19800	19902	0,51	70552	70855	0,43
σ_5	20002	20133	0,65	80201	80662	0,57

To assess the accuracy of the results, the plate was modeled in ANSYS [16]. The calculation of plates by the finite element method under two variants of the boundary conditions showed good convergence of the results obtained by the two methods (Table 1). The first three forms of buckling are given in table 2.

6 Conclusions

Thus, the stability problem for an orthotropic rectangular plate leads to four possible combinations of the roots of the characteristic equation of the problem, and, therefore, the complete solution of the problem will be determined

The roots of equation (8) form the spectrum of critical forces of the plate in question.

Let's look at some examples. We will determine the first three critical loads and three forms of buckling of a plate made of orthotropic material under two boundary conditions: hinged support along the entire contour (option 1) and rigid fixing of the plate on three sides with a free fourth side (option 2) (Fig. 2).

by 64 analytical expressions of fundamental functions.

The matrix of fundamental functions, which is the basis of the transcendental stability equation, is very sparse, which significantly improves the stability of numerical operations and ensures high accuracy of the results.

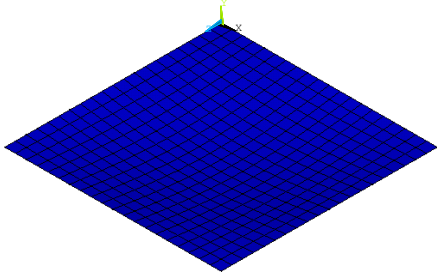

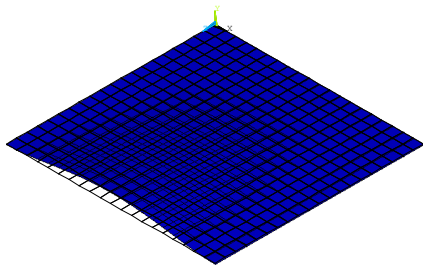

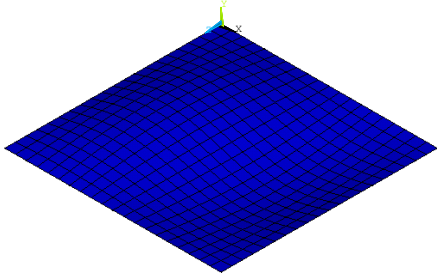

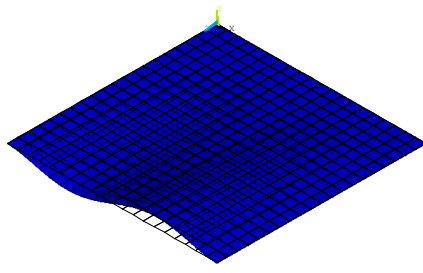

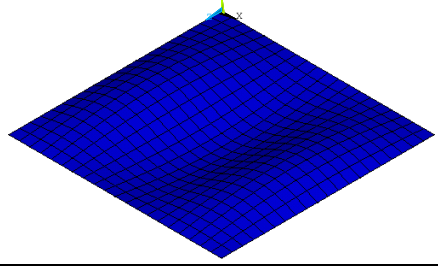

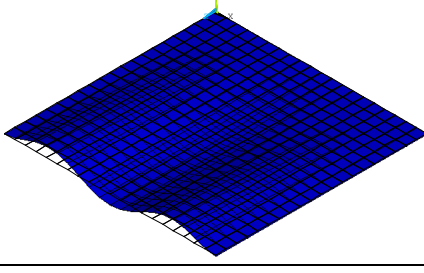

An analysis of the numerical results obtained by the author's method shows very good convergence with the results of finite element analysis. For both variants of the boundary conditions, the discrepancy for the corresponding critical loads is almost the same, and increases slightly with increasing critical load.

Moreover, this discrepancy does not exceed one percent. It should be noted that for both variants of the boundary conditions, the critical loads calculated by the boundary element method are less than in the finite element calculations.

The obtained transcendental stability equation allows one to determine critical forces both by the static method and by the dynamic one. From this equation it is possible to obtain a spectrum of critical forces for a fixed number of half-waves in the direction of one of the coordinate axes. For example, one half-wave in the direction of the axis Ox and many half-waves in the direction of the axis Oy (Fig. 1), two half-waves in the direction of the axis Ox and many half-waves in the direction of the axis Oy etc., depending on the magnitude of the coefficients A , B , K , C .

The proposed approach allows us to obtain a solution to the stability problem of an orthotropic plate under any homogeneous and inhomogeneous boundary conditions.

Selection of effective corrosion inhibitors for bischofite solutions and simulated medium of formation waters

*Viktoriia Dmytrenko**, *Yuriy Vynnykov*, and *Ivan Zezekalo*

National University "Yuri Kondratyuk Poltava Polytechnic", Department of Oil and Gas Engineering and Technology,
24 Pershotravneva Ave., Poltava, 36011, Ukraine

Abstract. Questions of the corrosion inhibitors selection for protection of oil-field pipelines have been studied in the article. Results of research of technological and anticorrosive properties of the corrosion inhibitors in mediums simulating industrial environments are presented. The methodological approaches to selection of the corrosion inhibitors on a stage of laboratory experiments on an example of Kaverdinsky gas-condensate deposits have been described. It was found that all the surfactants tested in the simulated medium of the formation waters show a protective effect of more than 90% with a dosage of 1 g/dm³. It is recommended to use bischofite solution with a mass fraction of 24% MgCl₂ and corrosion inhibiting 0.1% KI-1M admixture to protect industrial gas pipelines from carbon dioxide corrosion. This composition provides a degree of corrosion protection to 99.6%. The results of industrial tests confirmed the effectiveness of complex system – bischofite solution with a mass fraction of 24 % MgCl₂ and addition of 0.1% KI-1M corrosion inhibitor. The cationic surfactants KI-1M, St, SRK and amphoteric surfactants EM and KAPB effectively protect in simulating medium and provide a degree of protection from carbon dioxide corrosion to 91.2-98.9%.

Introduction

Corrosion is one of the main causes of equipment durability in the oil and gas industry, which causes huge economic losses and environmental damage [1-7]. Despite the progress made in combating corrosion destruction of gas equipment, more than 3000 failures of hydrocarbon collection systems pipelines because of internal corrosion are recorded annually.

Repair works of these breakages dramatically increases the cost of operating wells and hydrocarbon collection systems. Neglect of corrosion protection leads to frequent interruptions of work, and in some cases, at break of oil-well tubing to stoppage of hydrocarbon production. The main indirect losses from corrosion are underproduction due to emergency and repair stops, ecological sanctions.

The introduction of advanced technologies for the protection of operational equipment contributes to the reduction of labor and material costs, reducing the duration and cost of repair and rehabilitation works carried out at industrial enterprises [6]. These measures will ensure sustainable future development in the operation of oil and gas fields under conditions of carbon dioxide corrosion.

Important factors affecting degree and nature of corrosion damage are: 1) speed of gas-liquid flow; 2) tensile stresses of tubing; 3) volume ratio of water to hydrocarbon condensates in a liquid phase of flow; 4) inflow into the well of formation waters of different

salt composition; 5) influence of organic water-soluble acids [1, 6, 7].

The mechanism of carbon dioxide corrosion has been studied quite deeply and comprehensively [1, 8-11]. The intensity of corrosive destruction of equipment at CO₂ containing deposits is determined by partial pressure of carbon dioxide (at a low content of organic acids) and the temperature at which corrosion process takes place [1, 2, 4].

During the movement of gas through a wellbore, a liquid phase is released, resulting in a three-phase gas flow of gas-water-hydrocarbon inside the pipes. The intensity of corrosion in a three-phase system is mainly due to the structure and flow regime. Corrosive activity of medium in a well depends on ratio of hydrocarbons to water. According to some researchers, intensive corrosion of equipment begins with content of 0.1% of water in a well, then the corrosion rate remains constant, although the water content increases.

Key directions for improving corrosion control are use of: 1) inhibitors; 2) new designs and methods of application of insulating coatings; 3) various technological measures; 4) high-efficiency and economical pipes; 5) reliable and timely methods of inspection of existing pipelines without disturbing their mode of operation [1, 12].

One of the important methods to reduce corrosion of oil and gas equipment is to use of steel alloys and non-ferrous alloys, but their high cost limits widespread use of this highly effective method of corrosion control [1].

* Corresponding author: dmytr.v@gmail.com

Application of protective coatings in the fight against corrosion is also not widely used in practice. Metal coatings do not have sufficient protective properties under acid treatments at high temperatures, and are particularly sensitive to voltage concentrators. Non-metallic coatings are not capable to provide the required pipe surface insulation against corrosive agents and are merely a substrate for a thicker coating film of glass, enamel or polymer [12].

Inhibitory protection is environmentally sustainable in the future and one of the simplest, most effective and in many cases economically feasible methods of corrosion control [13-16]. Its undoubted advantage is the possibility of application without change of the corresponding technological processes and hardware design on already existing industrial projects. Other protection measures usually require replacement of existing equipment with new ones, which entails significant capital expenditures.

Therefore, it is advisable to consider the problem of selecting corrosion inhibitors to reduce the corrosive effect on gas equipment and the importance of laboratory research in solving this problem.

Problem statement

The results of laboratory tests are an important and objective measure of the rate of corrosive hazardous fluids action and are the basis for planning, analyzing, conducting and evaluating the results of anti-corrosion measures (in particular, the use of corrosion inhibitors). The higher the level of laboratory research used to select a corrosion inhibitor, the more reasonable are conclusions as to expediency of its use and, as a consequence, more targeted corrosion measures will be planned.

A distinctive feature of industrial piping systems is branching, presence of different diameters sections, a considerable number of local hydraulic resistances (latches, elbows, inserts, compensators, etc.). In addition, industrial pipelines are characterized by a continuous change in costs, phase and chemical composition of the transported products. The consequence of this is the instability and unpredictability of corrosive aggressiveness of the environment, localization of corrosion damage both along the route and along the intersection of pipes [14, 15]. All this causes the complexity of inhibitors choice problem and the technology of their application, the need for constant monitoring of effectiveness and sets up special demands to corrosion inhibitors themselves.

Corrosion inhibitors for industrial piping systems should be characterized by:

- 1) high protective properties in environments with constantly variable (sometimes in a wide range) chemical composition and hydrodynamic flow characteristics;
- 2) implementability – the possibility to use in existing technological schemes; stability of properties in processes of storage and use, taking into account climatic characteristics of a region;

- 3) cost-effectiveness – reagents should have an optimal price / quality ratio, taking into account the risks of operating specific industrial pipelines;

- 4) indifference – they should not have a negative impact on processes of transportation and processing of hydrocarbon products.

Almost all commercially manufactured corrosion inhibitors have their own sphere of application. This sphere is limited by technological features of equipment which is protected and by composition of corrosive active mediums.

The available range of modern corrosion inhibitors for oil and gas industry determines need for sound technological and economic choice of reagents, taking into account the operation peculiarities of various types of industrial pipelines. Laboratory researches play an important role in this selection. During laboratory process the following tasks are solved:

- simulation of corrosion processes in a real pipeline;
- detection of corrosion mechanism of steel grades of pipe;
- testing of inhibitor – selection of the most effective reagents for specific objects, specification of technology of their application;
- the identification of optimal application areas for specific inhibitor.

Therefore, selection of inhibitors for a specific oil and gas industry pipeline, or system of pipelines includes such stages:

- 1) analysis of technological characteristics of sites or system of industrial pipelines;
- 2) advance determination of reagents range, which suit to these conditions;
- 3) analysis of technological and anticorrosive features of inhibitors in laboratory conditions to detect the most effective ones;
- 4) bench and pilot tests of selected inhibitors.

The adoption of feasible practices of laboratory tests procedure for cleaning pipelines is shown schematically in Fig. 1 [9, 14, 15].

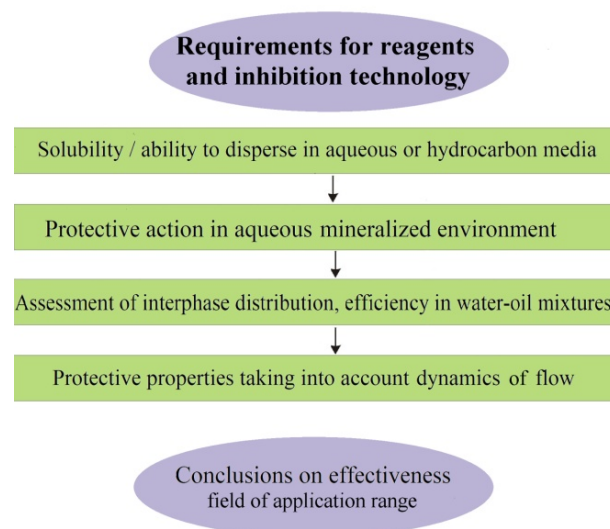

Fig. 1. Laboratory tests procedure for selection of corrosion inhibitors for gas pipelines.

Materials and methods

Brief characteristics and features of the methodology for conducting experiments on the selection of corrosion inhibitors in laboratory conditions are presented below. Work results carried out on the selection of corrosion inhibitors for the conditions of industrial pipelines of the Kaverdinsky gas condensate deposits, where the problem of carbon dioxide corrosion is acute, are submitted as an example. In addition, wells operation and industrial equipment are complicated by intensive hydrate formation. Corrosive activity of the transported medium by industrial pipelines is significant due to the high mineralization of water as a result of the use of bischofite solutions as hydrate formation inhibitor and the content of aggressive components CO₂ (up to 5.3%).

In laboratory conditions, studies were conducted on the selection of a corrosion inhibitor for conditions when bischofite is used as a hydrate formation inhibitor.

Bischofite solution has better antihydrate activity than calcium chloride, and no worse than methanol [17]. Currently, significant reserves of anhydrous magnesium chloride have been discovered in the Dnieper-Donets Rift; within borders of the Orchikivsk Depression, the estimated resources are about 10 billion tons. Commercially it is produced by washing mineral deposits of bischofite through a well. The cost of bischofite is much lower than methanol and calcium chloride. Bischofite is a nonvolatile, ecologically sustainable reagent [113].

Bischofite solution with a mass fraction of 24% MgCl₂ + 3 g/dm³ CH₃COOH was used to study effectiveness of the corrosion inhibitors. Concentration of acetic acid was chosen because of the maximum content of low molecular weight carboxylic acids in the formation waters of wells of Northeastern Ukraine. Lighted condensate was used as hydrocarbon phase, as it has neutral reaction of medium and constant fractional composition and as gaseous medium, carbon dioxide or oxygen.

Solubility of the reagents in the simulated medium was visually evaluated. Ability of reagents to form real or colloidal solutions and their stability were evaluated. As a result, 16 cationic and amphoteric surface-active substances were selected from more than one hundred surface-active substances that are highly soluble in aqueous solution. This indicates that the use of all reagents is possible in industrial gas pipelines transporting waterlogged products due to their high protective properties.

Thus, surfactants requirements were: 1) chemical structure of surfactants based on fundamental theoretical concepts; 2) coagulative stability in bischofite solution; 3) slight foaming; 4) protective anticorrosive action in hydrous mineralized waters; 5) thermal stability; 6) non-toxicity and safety for personnel and environment; 7) economic efficiency during industrial use.

The next stage is selection of reagents for protective properties based on evaluation of inhibitors protective effect in aqueous mineralized media ("bubble test"), rejection of ineffective ones, determination of applications spheres with respect to composition of

aqueous medium and preliminary determination of working dosages.

Research and evaluation of the protective effect of inhibitors was carried out in accordance with GOST 9.905-82 "Methods of corrosion tests. General requirements", GOST 9.502-82 "Metal corrosion inhibitors for water systems. Methods of corrosion tests", GOST 9.506-87 "Inhibitors of metal corrosion in water-oil environments".

Corrosive aggressiveness of the medium was evaluated by gravimetric method, according to loss of samples mass. Control experiment was without addition of reagents.

Corrosion tests were carried out on steel P-110 (table 1). This type of steel is widely used for tubing.

Table 1. Chemical composition of steel P 110.

C	Si	Mn	P	S	Cr	Ni	Cu
0.26-0.395	0.17-0.37	–	≤ 0.02	≤ 0.01	0.80-1.10	≤ 0.20	≤ 0.20

Corrosion studies were carried out in a thermostatic installation (Fig. 2.) The installation is designed at the All-Union Scientific Research Institute of Natural Gases and Gas Technologies (VNIIGAZ) for determination of corrosion rate in the simulated conditions of industrial pipelines [18]. It is a glass vessel in which the test solution was poured and a fluoroplastic cylinder with witness samples and a propeller stirrer was placed.

Fig. 2. Installation diagram for corrosion research:
 1 – thermostat; 2 – glass chamber; 3 – mixer; 4 – metal piece;
 5 – gas supply tube; 6 – fluoroplastic cylinder; 7 – cap;
 8 – hydraulic seal.

The cell was attached to an electric motor that rotated the stirrer. During rotation of the stirrer, circular fluid motions in the laminar mode were created in the fluoroplast cylinder with a flow rate of 0.3-0.5 m/s. When the propeller was mounted below the bottom of the cylinder, it was rotated at a speed of 1400 revolutions per second. There was a circular motion of the fluid in turbulent mode. The speed of stream flow in the area of placement of metal piece was 7-8 m/s. In addition to circular motion, fluid was also circulated through the small cylinder by creating irritation during rotation of the stirrer.

The corrosion rate of the metal was calculated by the formula [18, 19, 20]:

$$v = \frac{\Delta m}{S\tau} \quad (1)$$

where v – the corrosion rate $\text{g}/(\text{m}^2 \cdot \text{h})$;
 Δm – the loss of the metal piece, g;
 S – the surface area of the coupon, m^2 ;
 τ – the test duration, h.

Protective effect of test reagents in bischofite solution (Z) was calculated by the formula [18, 19]:

$$Z = \frac{v_0 - v_1}{v_0} 100 \quad (2)$$

where, v_0 – corrosion rate of the metal piece without the corrosion inhibitor e, $\text{g}/(\text{m}^2 \cdot \text{h})$;

v_1 – corrosion rate of the metal piece with the corrosion inhibitor e, $\text{g}/(\text{m}^2 \cdot \text{h})$.

Average permeability is calculated according to the mass loss [20]:

$$P = 8.76 \cdot v / \gamma \quad (3)$$

where P – permeability, mm/year;

8.76 – the conversion coefficient;

v – the corrosion rate, $\text{g}/(\text{m}^2 \cdot \text{h})$;

γ – metal density, g/cm^3 .

Quantitative indicators of the experiments were analyzed by methods of mathematical statistics with the calculation of average sample values, variance and errors of average values in groups of indicators. The significance of differences in the results obtained for different groups was determined by Student's t-test. Differences were considered statistically proven with a generally accepted probability of error $p < 0.05$.

Based on the results of preliminary studies, the following reagents were selected for further experiments: corrosion inhibitor KI-1M, cationic surfactants Stentex (St), Sulforocanol (SRK), amphoteric surfactants Emily (EM) and Cocamidpropylbetaine (KAPB):

KI-1M – acid corrosion inhibitor, cationic surfactant, a mixture of catapine and urotropine;

Stentex (St) – cationic surfactant, quaternary ammonium compound;

Sulforocanol (SRK) – cationic surfactant with the general formula $R - O - (C_2H_4O)_2 - SO_3$, where $R = C_nH_{2n+1}$; $n = 12 \div 14$ and a molecular weight of about 388.

Emily (EM) – amphoteric surfactant, the mixture of sodium and magnesium salts of lauryl and oleyl alcohols estersulfates;

Cocamidpropylbetaine (KAPB) – amphoteric surfactant, the fatty acid amide derivative with betaine structure.

In order to identify the possibility of combined application of a hydrate inhibitor, bischofite which is used in the deposits, and corrosion inhibitors under study, protective properties of inhibitors in bischofite solutions with concentration of 24% of $MgCl_2$ were determined.

Research results

The obtained dependences of corrosion rate on

concentration which are shown in Fig. 3, 4, allowed to isolate the minimum required concentration of reagents, for the test reagents – 1-2 g/dm^3 .

Fig. 3. Dependence of the corrosion rate of steel on the concentration of surfactants in bischofite solution in carbon dioxide environment ($w_{MgCl_2} = 24\%$, $T = 80^\circ\text{C}$, $3 \text{ g}/\text{dm}^3$ CH_3COOH , $t = 2 \text{ h}$, volume fraction of condensate 25% , $P_{CO_2} = 0.1 \text{ MPa}$).

Fig. 4. Dependence of the corrosion rate of steel on the concentration of surfactants in bischofite solution in an oxygen environment ($w_{MgCl_2} = 24\%$, $T = 80^\circ\text{C}$, $3 \text{ g}/\text{dm}^3$ CH_3COOH , $t = 2 \text{ h}$, volume fraction of condensate 25% , $P_{O_2} = 0.1 \text{ MPa}$).

The highest inhibitory effect in bischofite systems – low molecular weight carboxylic acids – carbon dioxide/oxygen at the content of reagents in a solution of $1 \text{ g}/\text{dm}^3$ revealed surfactants KI-1M, St, respectively, $83.5\text{-}96.2\%$ and $77.8\text{-}91.5\%$ (Fig. 5). The remaining reagents have a lower degree of protection at the appropriate concentration.

Due to mathematical data processing, polynomial and power mathematical models were selected. In an environment with O_2 , polynomial equations (Equations 4) give a low level of reliability of parameters, the obtained reliability indicators for the coefficients significantly exceed the level of 0.05

$$y = a_0 + a_1x + a_2x^2 + a_3x^3 \quad (4)$$

where, y – corrosion rate, $\text{g}/(\text{m}^2 \cdot \text{h})$;

x – concentration of inhibitor, g/dm^3 ;

a_0, a_1, a_2, a_3 – empirical coefficients.

In CO_2 environment, polynomial model in three cases out of six describes the experimental data as well

as the power data (in the presence of SRK, EM, KAPB).

Fig. 5. Protective effect of test reagents in bischofite solution ($w_{MgCl_2} = 24\%$, $T = 80\text{ }^{\circ}\text{C}$, $3\text{ g/dm}^3\text{ CH}_3\text{COOH}$, $t = 2\text{ h}$, concentration of surfactants 1 g/dm^3 , volume fraction of condensate 25% , $P_{CO_2/O_2} = 0.1\text{ MPa}$).

It should be noted that, in addition to the correlation coefficient, an important indicator of the adequacy of the approximation model is a residual error. The smaller the residual error value, the more accurate the model describes the experimental data. In all cases, residual error when using the power function (Equation 5) is significantly smaller than when using the polynomial, which indicates a much higher quality of approximation. For all inhibitors, the coefficients of the equation are reliably determined by $p < 0.05$

$$y = b_0 + (b_1x + b_2)^{-3} \quad (5)$$

where, y – corrosion rate, $\text{g}/(\text{m}^2 \cdot \text{h})$;
 x – concentration of inhibitor, g/dm^3 ;
 b_0, b_1, b_2 – empirical coefficients.

The coefficients and parameter estimates of nonlinear approximation equation are shown in Table 2, $p < 0.05$.

Table 2. Coefficients and parameter of nonlinear approximation equation 5.

Surfactant	Equation coefficients			Estimation of the approximation equation parameters		
	b_0	b_1	b_2	R	R^2	Residual error
For the O_2 environment						
KI-1M	1.35	1.28	0.34	0.999	0.9997	0.01
St	1.85	1.24	0.40	0.999	0.9999	0.02
SRK	5.21	0.93	0.43	0.999	0.9992	0.11
EM	3.41	0.60	0.42	0.999	0.9992	0.13
KAPB	3.21	0.60	0.41	0.999	0.9995	0.09
KAPB+KI-1M	2.49	0.65	0.41	0.999	0.9985	0.28
For the CO_2 environment						
KI-1M	0.28	2.85	0.48	0.999	0.9999	0.01
St	0.57	0.74	0.48	0.999	0.9978	0.15
SRK	4.16	0.26	0.57	0.999	0.9971	0.07
EM	3.14	0.24	0.54	0.999	0.9977	0.08
KAPB	2.35	0.15	0.52	0.998	0.9965	0.16
KAPB+KI-1M	2.20	0.32	0.52	0.999	0.9984	0.07

Produced formation water is corrosive-aggressive phase of extracting fluid. So the efficiency of complex systems (bischofite $24\%\text{ MgCl}_2$ + surfactants 0.1%) in relation to simulated medium of formation water is determined. The obtained data show (Fig. 6) that bischofite solution inhibits the process of carbon dioxide corrosion. All complex systems under study provide a degree of metal protection over $90\text{ }^{\circ}\text{C}$.

Fig. 6. Protective action of bischofite-based complex inhibitors against the reservoir model environment water ($w_{MgCl_2} = 24\%$, $T = 80\text{ }^{\circ}\text{C}$, $3\text{ g/dm}^3\text{ CH}_3\text{COOH}$, $t = 2\text{ h}$, concentration of surfactants 1 g/dm^3 , volume fraction of condensate 25% , $P_{CO_2} = 0.1\text{ MPa}$).

Comparative analysis of the data indicates the feasibility of using bischofite solution with a mass fraction of 24% of MgCl_2 and the addition of a corrosion inhibitor 0.1% KI-1M for protection of industrial gas pipelines from carbon dioxide corrosion, as long as this system provides a degree of protection against corrosion 99.6% relatively to stimulated medium of formation waters.

The results of industrial tests at the Kaverdinsky gas condensate deposits confirmed the efficiency of the complex system (bischofite solution with a mass fraction of 24% of MgCl_2 and the addition of a corrosion inhibitor 0.1% KI-1M). Rate of uniform corrosion with constant circulation of the inhibitor in the system did not exceed 0.01 mm/year .

The influence of the reagents on the corrosion rate and their protective effect in the simulated medium of formation waters was investigated. All tested surfactants in the simulated of formation water show a protective effect of more than 90% with a dosage of 1 g/dm^3 (Fig. 7), which satisfies the requirements of regulatory documents for corrosion inhibitors and allows them to be recommended for application at gas-fired facilities.

The protective properties of surfactants in the bischofite environment are 1.0 - 2.5 times less effective (Fig. 7). The protective effect of surfactants: SRK, EM and CAPB is especially noticeably reduced by 2.2 - 2.5 times. The KI-1M reagent in bischofite solutions practically does not change its effectiveness (increases by 1.1 times). A degree of protection of more than 90% was detected in the presence of surfactants St and KI-1M. In this regard, the use of SRK, EM and CAPB is appropriate for industrial gas pipelines that transport products with is low-mineralized aquatic environment.

Fig. 7. The degree of corrosion protection in bischofite solutions and simulated environment of formation water with a mass fraction of surfactants 0,1% (the inhibitor concentration is 1 g/dm³, T=80 °C, 3 g/dm³ CH₃COOH, t=2 h, concentration of surfactants 1 g/dm³, volume fraction of condensate 25%, P_{CO₂} = 0.1 MPa).

The obtained values of corrosion rate can be explained by the fact that the surfactants SRK, EM, and KAPB are capable of complexing with metals and are partially spent on the formation of complex compounds with magnesium and calcium ions which are in bischofite solution (Equations 6)

where, *Me* – the solvated metal ion;

J – an inorganic surfactant ion;

R – the hydrocarbon ion of the surfactant.

Nitrogen-containing surfactants KI-1M and St form a hydrophobic film on the surface of metal. This film is a barrier that shields the metal-corrosive environment. In most cases, surfactants are less polar than the components of the bulk phase, or have a low-polar radical. When adsorbed, surfactants replace polar surface with a less polar layer, equalizing polarity difference [15].

The effectiveness of complex inhibitors with respect to simulating environment of formation water in Northeastern Ukraine is represented in Figure 7. Data show that the corrosion rate in the bischofite solution is less than in the simulated medium of formation waters. The corrosion rate in the simulated medium of formation waters is 82.2 g/(m²·h), and in bischofite solution – 9.5 g/(m²·h) (Fig. 6) [19]. Such results are explained by the different concentrations of salts in the compared media and the different properties of the two salts (MgCl₂ and NaCl) in the high humidity environment. NaCl is more corrosive under immersion environment [21].

All investigated complex systems provide a degree of metal protection of more than 90 °C.

Thus, laboratory experiments to investigate the technological and corrosion properties of corrosion inhibitors are an important step in the selection of corrosion inhibitors for specific pipeline systems and sections. Despite the difficulty of accurately reproducing the technological conditions of corrosion of gas pipelines at the stage of laboratory experiments in condition of a

competent methodological approach to the experiments, it is possible to identify reagents that meet the requirements for their protective and technological properties to protect a specific gas industry.

It should be noted that laboratory testing is only the first step in the selection of an inhibitor – it allows to screen out the ineffective and to select the best ones for the next bench and industrial research. Laboratory testing is carried out under more severe conditions than actual tests (overestimated concentrations of CO₂ and O₂, short exposure time of the metal piece), so that the degree of protection is reduced compared to the real one.

Industrial tests of complex inhibitors proposed by the author for improvement of gas wells reliability under conditions of hydration and corrosion, were conducted at the Kaverdinsky gas condensate deposits of CJSC “Plast” for 30 days. The effectiveness of the complex inhibitor in preventing hydration was determined by monitoring the operation of well № 2 in hydration mode without supplying the inhibitor. The dew point of gas was determined by “Kharkov-2M” hydrometer, and the corrosion intensity was based on the testimonials that were installed in the samplers at the wellhead. Corrosion rate at constant circulation of the inhibitor in the system did not exceed 0.01 mm/year.

Conclusions

1. The basis of a complex inhibitor of hydrate formation and corrosion can be ecological sustainable bischofite solutions with the addition of amphoteric and cationic surfactants.
2. In order to reduce the corrosion effect of concentrated bischofite solution on the gas equipment of the Kaverdinsky gas condensate deposits, KI-1M and St inhibitors were selected, the inhibition efficiency of which in carbon dioxide and oxygen environment is 83.5-96.2% and 77.8-91.5 % respectively. The results of industrial tests confirmed the effectiveness of the complex system – bischofite solution with a mass fraction of MgCl₂ 24% and the addition of a corrosion inhibitor KI-1M 0.1%). The rate of uniform corrosion at constant circulation of the KI-1M inhibitor in pipelines did not exceed 0.01 mm/year.
3. The cationic surfactants KI-1M, St, SRK and amphoteric surfactants EM and KAPB effectively protect in a reservoir modeling environment and provide a degree of protection from carbon dioxide corrosion of 91.2-98.9%.

Abstract. In the article the diagnostic and regulation problems are considered for the rheological characteristics of mortars which are used for pumping into the interpipe gaps or cracks during repairing the pipelines, tunnels, and other objects. It is important to obtain the necessary mortar viscosity which allows providing a complete hole filling. For this aim the experimental dependencies have been determined between the injection mortar viscosity, the water-cement ratio, and the additives quantity in the mortars. According to the Poiseuille's flow law the theoretical dependencies have been obtained between the penetration depth of the injection mortar and viscosity under the different water-cement ratios. The said dependencies are a base during the development of the functioning algorithm the diagnostic and regulation system of the injection cement mortars rheological characteristics. The description of this functioning system is given. The mentioned system application allows increasing the cementation quality, corrosion resistance and durability of the repaired pipeline sections as well as decreasing of the work duration and labor costs.

1 Introduction

The injection technologies are widely spread for building and repairing of the infrastructure objects. These technologies include mortar injection – cementic, silicate, polymeric – into cracks, pores, seams, holes in building constructions, soil massives and/or between them. For example, the creation of a damp-proof layer against capillary rise by injection of chemical products is one of the most diffused methods, thanks to the relatively easy and cheap application [1]. In this case the hinder is overcoming capillary pressure in fine capillary pores. It requires an increase of the pumping pressure or the viscosity control.

The concrete permeability is becoming a serious problem for durability of hydraulic, water retaining and tunnel constructions due to the water influence or wet medium effect. To prolong service time and defence concrete and reinforced concrete constructions the various kinds of waterproofing are used: monolayer and multilayer ones, for cold and heated surfaces, with filler and without, as membrane or plaster. For each particular case it is necessary to come to a decision about the most effective method for the construction protection [2, 3]. The fiberglass plastics, which are wrapped around pipes, give them greater strength and corrosion resistance [4]. One of the most effective repair methods of sewage pipelines damaged by microbiological corrosion is polymer covering or laminate [5, 6]. The other way is a setting inside the pipeline a corrosion-resistant polymer

inserts or steel sleeves [7, 8, 9, 10, 11]. These inserts are placed in the damaged part of the sewage pipeline. A formed intertube gap is filled by polymer or cement mortar which quality defines reliability and durability of the restored sector (Fig. 1). The mortar injection is realized under pressure which is produced by piston or pneumatic mortar pumps 4 through special injector-packers 8. The mortar is transported from pumps by hoses-mortartransporters.

The movement depth of the mortar by the hoses into crack, interpipe gap, and etc. as well as the cementation quality (filling gap continuity, density, strength, water impermeability of hardened mortar) are determined by mortar rheological parameters – shear yield stress and dynamic viscosity. These characteristics most depend on the water quantity in the mortar, the type and quantity of plasticizing additives – anion-active surfactants. That is why during the injection process it is necessary to carry out ongoing diagnostics of mortar rheological properties. If necessary the rheological properties should be corrected by the change of the water quantity and/or plasticizing additives. The mentioned diagnostics and correction are very difficult for automation, and a specialist usually performs them (Fig. 1, a). Nowadays this system should be automatized and computerized (Fig. 2). The development of such systems is an actual task.

The investigation aim is justification and development of the automatic system for diagnostics and correction of cement injection mortar rheological properties.

The research tasks are:

- choice and rationale of the method which is applicable to automatic system for diagnostics of injection mortar rheological properties;
- finding out the dependences applicable to automatic system between the permeation depth and the mortar viscosity needed for penetration ensuring into the whole interpipe gap;
- finding out the dependences applicable to automatic system between the water-cement ratio and the mortar viscosity with and without additive-superplasticizer;
- developing of the automatic system algorithm for diagnostics and regulation of cement injection mortar rheological properties.

2 The choice of the diagnostic method for injection mortars rheological properties

The choice has been carried out based on the analysis of the exist systems for automatic diagnostics and regulation of building materials technological parameters, in particular viscosity. Many researchers consider that rheological approach is more accurate and reliable compared with the traditional tests. Therefore, it is increasingly used in the different technological processes related to mixtures pumping. The studies on concrete pumpability combining different laboratory tools and linkage to rheology are conducted in [12, 13]. The correlation between the rheological properties and the concrete pumpability are analyzed under various temperatures and time after mixing. As the pumpability characteristics the Bingham parameters and slippage resistance are chosen. The predictive capacity of the tribometer concerning the concrete pumpability is validated by measuring the discharge pressure. Also, it has been demonstrated that knowledge of the rheological properties of the lubrication layer is not sufficient to state whether the concrete is pumpable or not. Only a combination of rheological instruments makes the adequate description of concrete pumpability possible.

The yield stress and plastic viscosity values are necessary to ensure adequate filling ability and concrete stability for successful casting of prestressed elements. According to the results [14], it is recommended the concrete to have plastic viscosity within 30-130 Pa·s to provide its proper workability. Higher viscosity levels should be avoided due to its limitation in passing ability. Understanding of the rheological parameters is important for developing the quality control test methods. As it is shown in [15], the concrete rheology affects the surface quality. It is found out that the concrete mixtures with the yield stress lower than 25 Pa provide the best surface quality.

The science of rheology is increasingly used to describe the properties of fresh cement paste. Compared to standard workability tests, rheological properties allow carrying out more fundamental investigation, more precise phenomenological description of flow properties and serving as input for numerical simulations [16]. However, when the cement researchers use rheometers the results depend very much on choice of protocol and

tested material. Unfortunately, there is no single procedure that works for all rheometers and there is no rheometer that works for all materials. Hence, the search of reliable way for rheological properties diagnostics is still being continued. For these aims researchers suggest the different methods for the rheological properties control: oscillatory rheology [17], ultrasonic spinning rheometry [18], rotational viscometer and dynamic shear rheometer [19].

The workability of mortar and concrete could be evaluated in terms of their flowability and deformability during pumping and filling operations. However, there is no rheological criterion yet upon which the dynamic stability could be evaluated [20]. To predict and control the concrete behavior numerous studies are performed in [21]. The results demonstrate that there is no clear relationship between flow resistance and piston pressure. By contrast, fairly good statistical correlations exist between torque viscosity and piston pump pressure. Therefore, the torque can be the rheological parameter for the mortar and concrete workability. Based on this, the special sensors can be acceptable for diagnostics of injection mortar rheological properties. These sensors consist of two parts – mechanical and electrical. The mechanical part contacts with mortar and electrical one is placed outside mortar or isolated from it. The sensor can be proposed as such device in [22] and in which the electric motor translationally moves a spherical spindle inside the mortar. This sensor is based on amperage conversion on the motor shaft to the rheological characteristics with the usage of dependencies determined earlier. But for the such system the dependencies have not still been established between the mortar rheological properties and the mortar viscosity which are necessary for penetration ensuring into the whole interpipe gap as well as the dependencies are not established between the mortar penetration depth into gaps, cracks, seams, and the mortar rheological properties. The influence the water quantity in the mortar and quantity of plasticizing additives on the mortar rheological properties is not established either.

3 Theoretical bases and experimental studies

To define the above mentioned dependencies a flow process of cement mortar (suspension) as a water-dispersion system is analyzed in the annular gap (slotted gap for crack) with thickness a . The mortar flows in the annular gap (crack) under pumping pressure p while an external pressure opposes it. The external pressure is formed by the ground water pressure or water pressure p_h which remains after washing of the interpipe gap. Also the external pressure includes the pressure p_f formed by friction force F along gap walls. As a result of pressure equalization, a stationary flow with speed v is installed. Since the penetration is performed at depth l during injection time τ it can be taken

$$v = l/\tau, \text{ m/sec.} \quad (1)$$

In case of a big gap thickness a and filling gap by water, the effects considering meniscus formation can be neglected. According to the Poiseuille's flow law the internal friction force equals

$$F = \eta S_s v / \delta, \quad (2)$$

where η is the effective dynamic viscosity of the mortar, s/m^2 ; v/δ is the mortar flow rate gradient, $1/\text{s}$; δ is the mortar near-wall layer thickness in which water speed is changed from 0 to v , m ; S_s is the gap surface area, m^2

$$S_s = [\pi d + \pi(d+a)]l = \pi l(2d+a), \quad (3)$$

where d is internal diameter of the annular gap, m .

After substitution (3) in (2) it is obtained

$$P_f = \frac{F}{S} = \frac{\eta S_s v}{S \delta} = \frac{\eta v \pi l(2d+a)}{\pi h(d+0.5a)\delta} = \frac{2\eta v l}{a\delta}, \quad (4)$$

where S is an annular gap surface area, m^2

$$S = \pi(d+0.5a)a = \pi a(d+0.5a). \quad (5)$$

The stationary flow is installed under condition

$$p = p_h + p_f. \quad (6)$$

Having substituted (4), and then (1) in (6), it is obtained

$$p - p_h = \frac{2\eta v l}{a\delta} = \frac{2\eta l^2}{a\delta\tau}. \quad (7)$$

After transformation (7), the mortar injection depth dependence in the gap from the gap thickness a and a mortar viscosity η is obtained

$$l = \sqrt{\frac{(p-p_h)a\delta\tau}{2\eta}}, \quad (8)$$

and the viscosity dependence η which is required for the penetration depth ensuring l in the gap thickness a

$$\eta = \frac{(p-p_h)a\delta\tau}{2l^2}. \quad (9)$$

Investigate the dependence of the mortar penetration depth l (8) as a function of the interpipe gap thickness (crack disclosing) a . The bounding conditions are the quantity characteristics of the reviewed constructions and technologies: the repair section length – less than 100 m; the annular gap thickness – $0 \div 20$ mm in a bench flume and less than 100 mm in an arch; the proof-test pressure – less than 0.16 MPa (it is limited in a pump possibility and pipe strength); the proof-test pressure time – about 10 min; the mortar working life – bigger than an hour (it is limited in an injection duration).

For calculations on (9) the hydrostatic pressure of water which is displaced during proof-test pressing is taken equal for the case when water ground level is higher at 3 m from a sewer pipe. So, the water column height $h = 3$ m, and the hydrostatic pressure equals

$$p_h = \rho \cdot g \cdot h = 1000 \cdot 9,81 \cdot 3 \approx 30000 \text{ Pa,}$$

where ρ is the water density, 1000 kg/m^3 ; g is the gravity acceleration, 9.81 m/s^2 .

The proof-test pressure p is accepted equal 160000 Pa , the proof-test pressure time τ is assumed to be 600 s . The mortar near-wall layer thickness δ in which water speed is changed from 0 to v is assumed to be $2.5 \cdot 10^{-5} \text{ m}$ for the mortar without additives, and $0.8 \cdot 10^{-6} \text{ m}$ for the mortar with additives [23, 24]. After appropriate substitutions the equation (8) takes the form for the mortar without and with additives, accordingly

$$l = 31.2 \cdot (a/\eta)^{0.5}; l = 55.9 \cdot (a/\eta)^{0.5}. \quad (10)$$

The hardened mortar should possess water impermeability which is not less than concrete impermeability of the pipes used for free-flow collectors building. The concrete water impermeability of such constructions should be W4 according the National Standard [25]. The number “4” means the pressure in atm under which the water penetration does not occur after keeping the concrete samples during determined time under pressure. For concrete the mentioned impermeability class is provided with water-cement ratio (W/C) less than 0.6 . Since the concrete permeability is mainly depended on the cement stone properties, it is necessary also to accept W/C less than 0.6 for the injection mortar. The impact degree of an operational medium to the sewer collector is highly aggressive chemical environment XA3 according to [25, 26] taking into account pH value. Under this condition the concrete water impermeability class should be increased to W8 which is provided with W/C less than 0.45 . Therefore, the mortar W/C value for the interpipe gap cementation should be taken not more than 0.45 but it is advisable even less based on the conditions ensuring the water impermeability and corrosion resistance as well as durability of the collector constructions. Such W/C ratios can be achieved only with the usage of cementitious mortar with additive-superplasticizers based on the conditions mortar pumping by pumps.

Define the experimental dependencies between dynamic viscosity and W/C ratio. The dynamic viscosity values have been determined with the usage of the rotational viscometer. For studies the cement-water suspension has been performed with different water-cement ratios and addition of the superplasticizer (sodium salt of polymethylene poly-naphthalene sulfonic acid). The experimental results are given on the Fig. 3.

For calculations on the formula (10) the mortar dynamic viscosities η are taken according to Fig. 3:

- for the mortar without additives with W/C = 0.6 – $0.125 \text{ Pa}\cdot\text{s}$, with W/C = 0.45 – $0.27 \text{ Pa}\cdot\text{s}$, with W/C = 0.35 – $2.33 \text{ Pa}\cdot\text{s}$;
- for the mortar with additive-superplasticizer with W/C = 0.6 – $0.002 \text{ Pa}\cdot\text{s}$, with W/C = 0.45 – $0.01 \text{ Pa}\cdot\text{s}$, with W/C = 0.35 – $0.061 \text{ Pa}\cdot\text{s}$.

Graphic presentations of the calculations by formula (10) are given on Fig. 4.

As it follows from Fig. 4 the cement mortars without additives with W/C= 0.45 – 0.6 do not penetrate into the interpipe gap for the distance more than 40 m .

CWS – ordinary mortar (cement-water suspension);
 SPCWS – mortar with additive-superplasticizer
 (superplasticized cement-water suspension)

Fig. 3. The dependence between the cement mortar dynamic viscosity η and the water-cement ratio W/C.

Fig. 4. The dependence between the penetration depth l of the injection mortars and the interpipe gap width (crack) a .

The mortars with additive-superplasticizers with $W/C = 0.35 \div 0.45$ penetrate for the distance to 100 m. Such W/C ratios provide the necessary water impermeability and corrosion resistance of a cement stone. Thereby the cement mortar with W/C not more 0.45 should be applied for cementation of the interpipe gap during a new pipeline arrangement inside damaged sewage collectors. When the repair section length is not more than 20 m the mortar without additives is suitable for the usage. If the length is from 20 m to 100 m the usage of additive-superplasticizer is required.

To sum, the dependence (9) between the required mortar viscosity and the interpipe gap width as well as the repair section length (penetration depth) is applicable for the automatic diagnostic system. The dependence the W/C ratio as a function the required viscosity can be obtained after an approximation of the dependencies given on Fig. 4.

4 Algorithm development for automatic system

Among the automatic systems for diagnostics and regulation of the building object parameters there is a system which allows diagnosing the wet state and stability of the ground massive [27]. This system uses the coaxial sensors with capillary backfill contacting with ground. The bigger soil wet the bigger backfill wet. The sensor measures electrical resistance or electrical capacitance of the backfill. Then these values are digitized and transformed to the ground wetness parameter using the analytical dependencies. The system informs an operator about the moisture amount. If it is provided for, the system generates control signal for actuating mechanisms which perform draining or fixing the ground. If suchlike mechanisms are absent the system recommends to the specialist to choose certain methods for draining or fixing the ground. However, this system is automatic in part and expert partially. Besides the used sensors are suitable for not too large quantities of wetness for dispersed material such as soil. These values can be significantly less than the water content of the injection mortar. Also, such sensors are not applicable in case of an addition of the hardening accelerators-electrolytes into the injection mortar.

The magnitude of the mechanical effort to move the mobile part of the device to measure the shear stress can be converted into an electrical signal. For this research, an electromechanical device ES-1 (Fig. 5) was developed in which the measuring spindle is a sphere which is driven by the electric drive and moves at a constant speed. The measuring scale is an ammeter, which shows the strength of the current on the shaft of the electric motor and which is pre-set with the desired workability index of the mortar. A control signal is taken from the shaft of the electric motor, for the automated control system to prepare the building mortar. The current strength can be used as the conventional viscosity of the mortar, and the dependence can be applied to automatic maintenance of water content and given technological characteristics.

Fig. 5. Electromechanical device for determining the rheological and technological characteristics of building mortars: 1 – tripod; 2 – electric drive; 3 – rod; 4 – spherical spindle; 5 – ammeter; 6 – building mortar; 7 – computer.

An algorithm of the developed automatic system for diagnostics and regulation of rheological properties for the cement injection mortars is given on Fig. 6. The algorithm functions in the following way. The operator, who performs the system work, with the help of statement 2 inputs the values of the length L , the interpipe gap width δ , the maximum permissible deviation of mortar viscosity $\Delta\eta_{max}$, the maximum permissible water content in mortar W_{max} , the interpipe gap volume V_{max} including hollows and cavities in the damaged places, the mortar mixer volume of discrete action v . Statement 3 calculates the permissible mortar viscosity η depending on L and δ , and operator 4 counts the water consumption W depending on η .

Statement 5 assigns the value 0 for number of the mortar preparation cycle i . Statement 6 compares the water consumption W with the maximum permissible water content in mortar W_{max} . If $W > W_{max}$, statement 7 assigns W the value W_{max} , and statement 8 calculates the additive-superplasticizer consumption A depending on W_{max} and the required mortar viscosity η . If W is not bigger than W_{max} , statement 9 assigns the value 0 for the additive-superplasticizer consumption A . Statement 10 increases the number of the mortar preparation cycle i by 1, and statement 11 outputs the number of the mortar preparation cycle i , the consumption of water W and additive-superplasticizer A , the required viscosity η for information of the specialist, as well as transmits the value W and A to actuating mechanisms of batchers.

The batchers dose the mortar components into the mortar mixer that prepares the mortar. After that the mortar viscosity diagnosing is performed by the electric drive-ball sensor, and the mortar is pumped by the pump through the mortar conduit into the gap. Amperage I from the sensor of the motor shaft is digitized with the usage of a converter and input in the algorithm by statement 12.

Statement 13 converts amperage to the mortar viscosity η_i . Statement 14 counts the mortar total amount V which entered into the gap after i -th cycle, and statement 15 compares the obtained value V with maximal volume

of the interpipe gap V_{max} . If $V < V_{max}$ statement 16 calculates the deviation made by the diagnostic system, the viscosity value η_i from the demanded viscosity η .

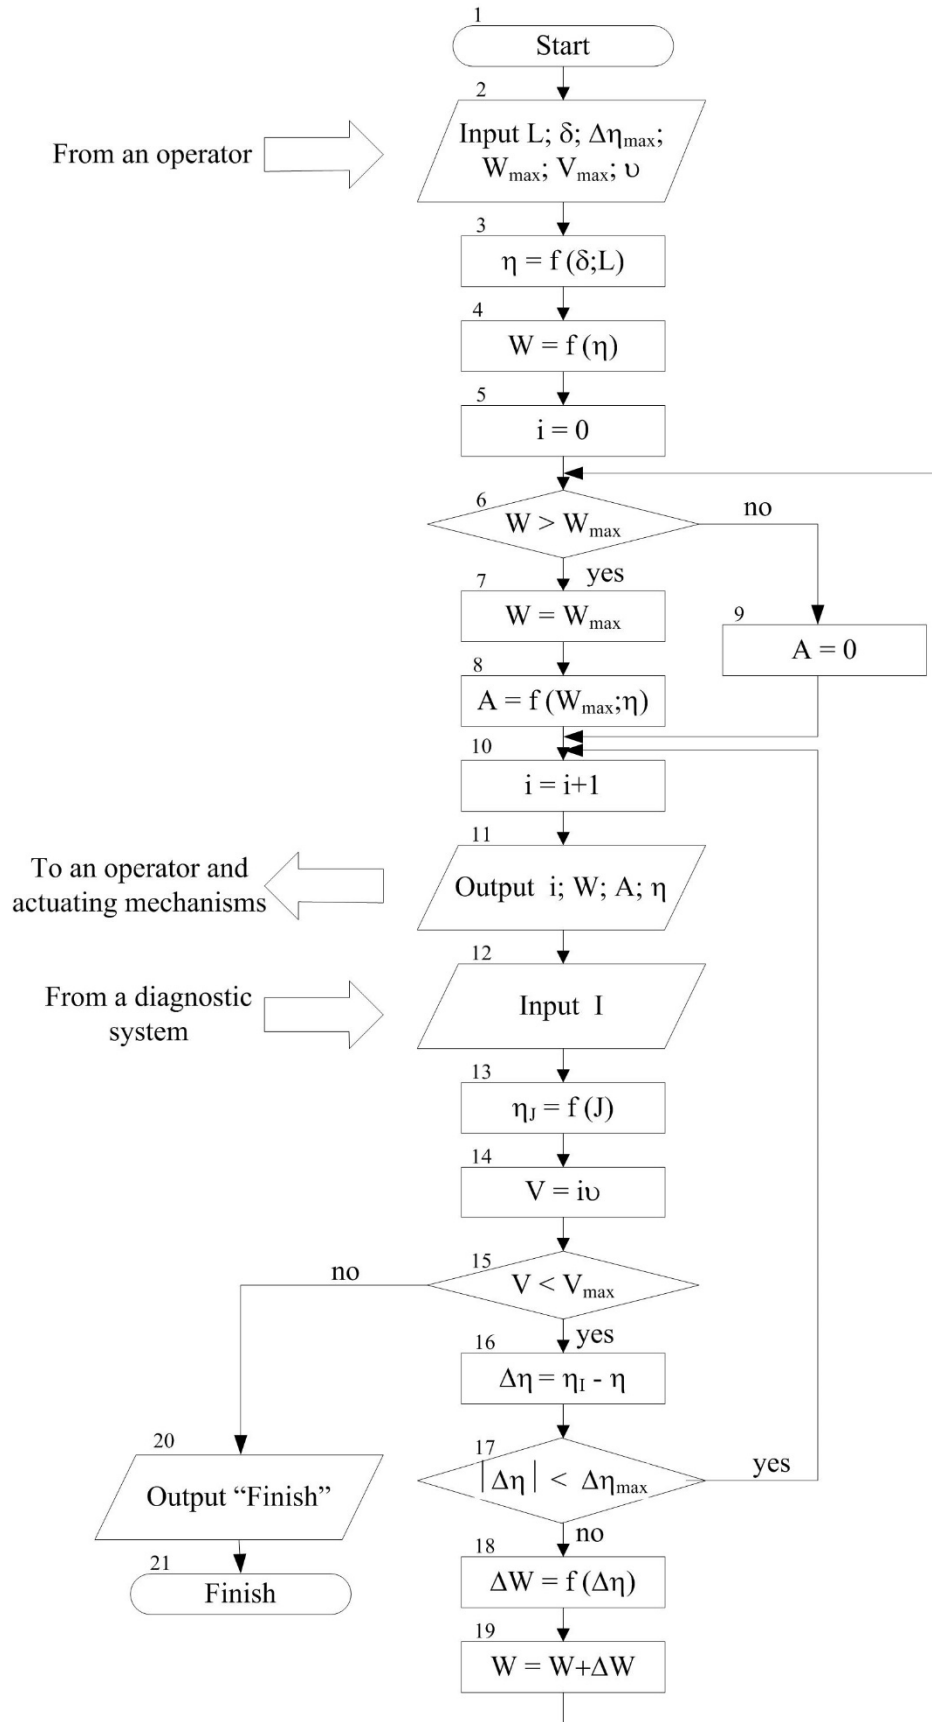

Fig. 6. Functioning algorithm of the diagnostic and regulation system of the injection mortars rheological characteristics.

Statement 17 compares the absolute value of the viscosity deviation $|\Delta\eta|$ which is defined by statement 16 with the maximum permissible value $\Delta\eta_{max}$. If $|\Delta\eta| < \Delta\eta_{max}$ statement 17 returns the executing programme to statement 10. If $|\Delta\eta|$ is not less than $\Delta\eta_{max}$ statement 18 calculates the correction of the water consumption ΔW depending on the viscosity deviation $\Delta\eta$, and statement 19 counts the new corrected water consumption W and returns the executing programme to statement 6. If V is not less than V_{max} statement 20 reports about the work completion, and statement 21 ends it.

Conclusions

1. The electromechanical sensor is chosen for the automatic diagnostics and regulation system of the rheological characteristics for the injection mortars which are used for repairing the sewage pipes by the insert method. The sensor mechanical part contacts with the mortar but the electric part is placed outside the mortar. An electric signal – amperage – is removed from the motor shaft which translationally moves a spherical spindle inside the mortar. After digitizing the amperage is transformed to the mortar viscosity value.
2. The dependencies between the mortar viscosity, the penetration depth, and the water-cement ratio of the cement mortar both without the additives and with the additives-superplasticizer are received. These dependencies are applicable for the automatic diagnostic and regulation system of the rheological characteristics for the injection cement mortars.
3. Functioning algorithm of the automatic diagnostic and regulation system of the injection mortars rheological properties is developed for cementation of the interpipe gap during repairing the sewage pipes by the insert method. The system application allows increasing of the cementation quality, corrosion resistance and durability of the repaired pipeline section as well as decreasing the work duration and labor costs.

²Lublin University of Technology, Department of Building Structures, 40 Nadbystrzycka Str., 20-618, Poland

Abstract. Sustainable development depends on a consistency of interests, social, ecological and economic, and that the interests are evaluated in a balanced manner. In order to reduce CO₂ emissions, the conception of decreasing clinker factor and increasing the role of supplementary cementitious materials (SCMs) in the cementitious materials has high economical and environmental efficiency. The performance of clinker-efficient blended cements with supplementary cementitious materials were examined. The influence of superfine zeolite with increased surface energy on the physical and chemical properties of low-carbon blended cements is shown. Increasing the dispersion of cementitious materials contributes to the growth of their strength activity index due to compaction of cement matrix and pozzolanic reactions in unclinker part. In consequence of the early structure formation and the directed formation of the microstructure of the cement matrix is solving the problem of obtaining clinker-efficient concretes. Shown that low-carbon blended cements with high volume of SCMs are suitable, in principle, for producing structural concretes.

1 Introduction

The development of civilization, such as urban expansion or infrastructure development, has a significant environmental impact. Excessive consumption of energy leads to a significant increase in the amount of carbon dioxide in the atmosphere, which causes climate change and threatens the future of humanity. At the same time there are problems of waste disposal and reduction of consumption of natural raw materials. Therefore, the crucial topic of the functioning of civilization in the XXI century is the concept of sustainable development [1, 2]. The priorities identified at the World Summit on Sustainable Development are the integration of these three components: economic growth, social development and environmental protection. Currently, the challenge of introducing principles of sustainable development in the construction sector, especially in the industry of construction materials, is extremely urgent. This implies the creation of technical prerequisites that form the basis for the development and implementation of effective measures to improve the energy efficiency of construction technologies in accordance with environmental requirements, taking into account the full life cycle of products and objects. The basic principles of sustainable development strategy in the cement industry are to optimize the usage of non-renewable natural raw materials: the implementation of resource-saving technologies; utilization of industrial waste, as well as comprehensive environmental protection and reduction of CO₂ emissions [3-6].

The Paris Agreement was adopted in accordance with the UN Framework Convention on Climate Change

(UNFCCC) in order to regulate carbon dioxide reduction measures from 2020 replacing the Kyoto Protocol. This climate agreement stipulates that commitments to reduce harmful greenhouse gas emissions to the atmosphere and not to exceed rising temperatures above 2 degrees Celsius shall be observed by all states, regardless of their level of economic development.

The EU's priority is to reduce greenhouse gas emissions by 80-95 % by 2050. The cement industry produces a significant amount of greenhouse gases, accounting for 2-2.5 gigatons of CO₂ or 6.5 % of the total anthropogenic emissions worldwide. Integrated cement industry solutions for sustainable development policies aim at reducing CO₂ emissions by reducing high-energy Portland cement clinker in composition of cement by utilizing industrial waste, improving production technology and using alternative fuels. Additional emission reductions can be achieved through the use of new technologies such as carbon capture and storage (CCS) and low carbon cement replacement components [7]. With this policy and technological prerequisites, a potential reduction in CO₂ emissions of up to 80 % can be achieved [8]. The production of high-tech products in the construction industry, taking into account the reduction of environmental pollution, is largely realized through the introduction of effective low-emission (low-carbon) cements and concretes based on them [7].

The EU Roadmap 2050 on low-carbon economy with regards to cement and concrete industry envisages five parallel directions, each contributing to the reduction of CO₂ emissions. According to the roadmap, the first direction involves reduction of the usage of natural resources, increasing the share of alternative fuels,

* Corresponding author: msanytsky@ukr.net

replacing clinker with mineral components and introducing new types of cement, which will allow to replace a significant proportion (up to 80 wt.%) of high-energy Portland cement clinker in cement-containing materials, including production wastes. The use of SCMs in cement production has a positive impact on the economic aspect of production and, crucially, is a significant factor in improving the environment. On the other hand, the use of industrial waste can reduce the consumption of natural raw materials, reduce CO₂ emissions and free up useful soils, which will reduce the risk of man-made disasters and contribute to the energy independence of the national economy [8].

The family of common cements according to EN 197-1 are divided into five types: CEM I – Portland cement; CEM II – Portland cement with additives; CEM III – slag Portland cement; CEM IV – pozzolanic cement; CEM V – composite cement. Portland cement CEM I can contain up to 5 wt.% of mineral additives. The content of mineral additives in cement from CEM II to CEM V can vary over a wide range – from 6 to 80 wt.%. In the European standard EN 197-1 are selected as a separate type of composite cements, which according to the requirements must contain at least two types of mineral constituents of different nature of activity (hydraulic and pozzolanic action).

The solution to the problem of energy saving and reduction of CO₂ emissions in the cement industry is largely determined by the search for structural, logical and environmental ways of replacing part of the Portland cement clinker with secondary components with optimization of particle size and material composition of cement. The result of such efforts is a plan of amendments to the standard for general purpose cements EN 197-1 regarding the introduction of new types of composite cements of types CEM II/C and CEM VI [9].

Due to the environmental impact of the cement industry in the direction of sustainable development, by selecting appropriate combinations of non-clinker components in low-carbon cements will be an alternative to traditional cements [10-13]. At the same time, more and more attention are paid to the production of low-carbon concretes. The evaluation of the environmental impact indicator for binary and ternary cements has made it possible to determine their suitability for the production of low-carbon concrete.

The concept of creating modified concretes and mortars involves the use of multicomponent cements with a high content of SCMs and optimization of their component composition and particle size distribution due to the combination of mineral components of natural and man-made origin, nanoadditives and alkaline activation [14-17]. This will facilitate the acceleration of hydraulic and pozzolanic reactions in the SCMs system; improving the transition zone between the cement matrix and the aggregate. Increasing the content of finely dispersed energy-active fractions in the SCMs will increase the surface area of the active phases, which increases the rheological effect of the polycarboxylate modifier on the mixture. The effectiveness of this idea is to maximize the disclosure of the synergistic role of ultrafine mineral components in low-emission multicomponent cements,

which will have a direct impact on the processes of regulating the properties of clinker-efficient concretes.

According to data from K. L. Scrivener et al. [5], binder intensity for concretes with a strength of 60 MPa should be within the range of 2-5 kg per 1 MPa of concrete strength (Fig. 1). Binder intensities around 4-5 kg/m³·MPa can be achieved for 50 MPa concretes and more with by optimizing the component composition of concrete and using new generation water-reducing admixture. Similar way can be deployed for mortars, concrete blocks and other cement-based products.

Fig. 1. Potential CO₂ mitigation by optimizing binder use with current and high-filler, low-water technologies [7].

In advanced EU countries, CO₂ emissions for concrete have been reduced by 19.1% and account for 83.4 kg of CO₂ per tonne of concrete. To reduce ECO₂, it is also foreseen to replace the proportion of Portland cement CEM I pure cement in concrete with multicomponent SCMs, which is an actual way to achieve a sustainable development in construction.

2 Materials and methods of research

2.1 Materials

Commercially available Ordinary Portland cement (OPC) CEM I 42.5R (Manufacturer – JSC “Ivano-Frankivsk Cement”, Ukraine) was used as reference cement in the investigation. The contents of the main clinker phases were as follows, mass. %: C₃S – 60.2; C₂S – 4.25; C₃A – 7.20; C₄AF – 11.85. Supplementary cementitious materials as ground granulated blast furnace slag (GGBFS, Kryvyi Rih), zeolite tuff (Z, Sokyrnytsky quarry), fly ash (FA, Burshtyn TPP), and limestone powder (LL, Dubivetske quarry) were used to obtain low emission binders. The chemical composition of SCMs is shown in Fig. 2.

Building binder G-6 brand based on calcium sulphate hemihydrate (CaSO₄·0.5H₂O) was used for development low-carbon gypsum binder.

The high-performance Master Glenium ACE 430 (BASF) polycarboxylate ether (PCE) superplasticizer was used as a modifier for concrete and air-entraining admixture MasterAir 81 (BASF) was used to improve the quality parameters of mortars.

Fig. 2. Chemical composition of SCMs.

Sand of Zhovkva deposit, Ukraine, was used as fine aggregates (FA) and crushed stone of Virovske deposit, Ukraine, as coarse aggregates (CA) were used to design of mixture compositions.

Blended cements (CEM II/B-M, CEM IV/B, CEM V/A, MC 22.5X) with the different ratio between Portland cement CEM I 42.5R and supplementary cementitious materials were used in experiments (Table 1).

Table 1. The composition of cements.

Cement	Clinker factor	OPC	GGBFS	Z	FA	LL
CEM I	0,95	100	-	-	-	-
CEM II/B-M	0,65	65	20	10	-	5
CEM IV/B	0,50	50	-	27	23	-
CEM V/A	0,50	50	25	20	-	5
MC 22.5X	0,40	40	-	40	-	20

2.2 Methods

Investigation of the chemical composition of OPC and SCMs was carried out using an X-ray diffractometry ARL (OPTIM'X) 9800XP. Blended cements were obtained by mixing OPC and SCMs in a laboratory ball mill. The physical and mechanical properties of blended cements were determined in accordance with current standards and generally accepted methods. For determining the strength class of cement according to EN 196-1 the specimens (40x40x160 mm) of the mortar based on investigated cement were prepared. After disbandment and marking, the samples were placed in water for storage until the test was performed at 2, 28 and 365 days.

To establish relationship between ecological and technical properties of concrete, clinker efficiency coefficient in concrete was determined as the ratio of cement consumption to compressive strength in a certain age [kg/(m³·MPa)]. Compressive strength of nanomodified concretes was determined on cubic specimens (100x100x100 mm) after 1, 2 and 28 days.

3 Research results

Component composition of blended cements have a significant influence on the process of the compressive strength. The compressive strength of cements at age of

hardening 2; 28 and 365 days is shown in Fig. 3. Early strength of blended cements is lower compared to OPC, because SCMs are characterized by lower activity than Portland cement clinker. However, after 28 days of hardening the strength of the blended cements CEM II/B-M, CEM IV/B, CEM V/A increases and corresponds to the strength class 32.5 R and MC - the strength class 22.5X. Coefficients of CO₂ emission of blended cements with different clinker-factor are presented at Fig. 4.

Fig. 3. Compressive strength of cements.

Fig. 4. CO₂ emission of blended cements with different clinker-factor.

To determine effects of formulation and technological factors, concrete mixes compositions were designed using mathematical experiment planning. Experimental studies of impact of composite Portland cement CEM II/B-M and PCE superplasticizer consumption on early strength as well as clinker efficiency coefficients in concrete were performed according to a two-factor three-level experiment. Consumption of CEM II/B-M ($X_1=320; 370; 420$ kg/m³) and amount of PCE ($X_2=0; 0.8; 1.6$ wt. %) were chosen as variable factors.

The increase of cement usage from 320 to 420 kg per m³ to achieve OK=16–18 cm, a decrease in W/C from 0.62 to 0.48 was observed. After 2 days of curing, modified concrete with cement amount of 420 kg/m³ and PCE of 1.6 wt. % had the highest strength ($f_{c2}=47.0$ MPa). Calculations of concrete clinker efficiency revealed that with an increase in strength of concrete, specific consumption of clinker per unit of strength is 3.5...3.1 kg/m³ MPa after 28 days. The modified clinker-efficient concretes classes C35/45...

C40/50 are characterized by average increase of strength ($f_{cm2}/f_{cm28} = 0.32...0.39$).

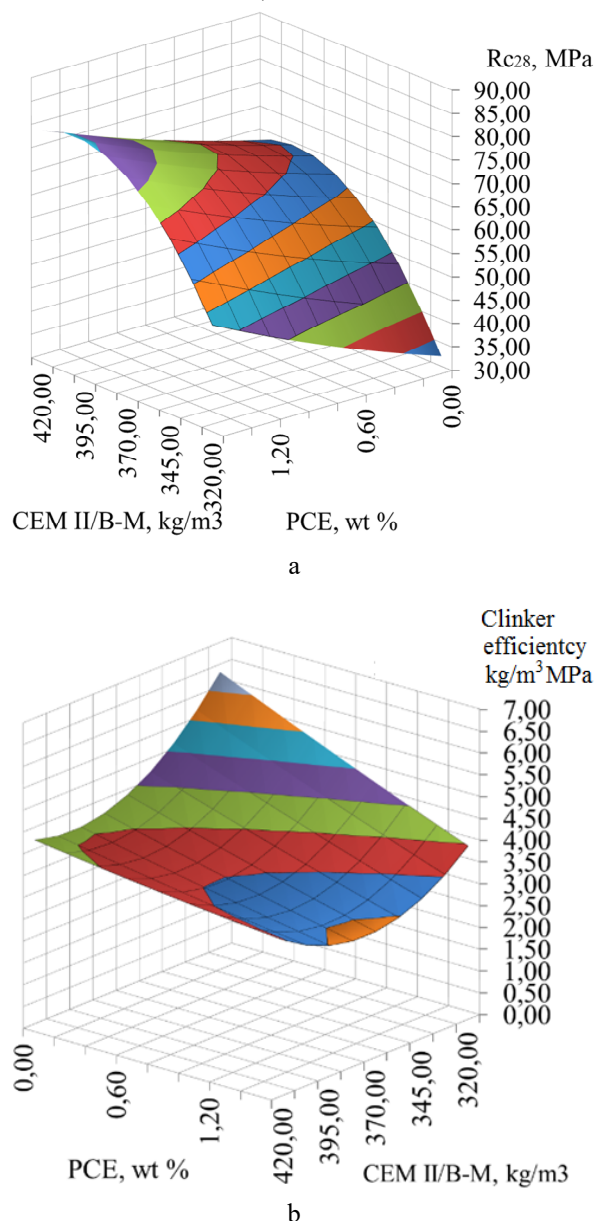

Fig. 5. Response surfaces after 28 days of hardening: concrete strength (a) and clinker efficiency (b).

Concretes with $W/C = 0.38-0.42$ were designed to study the quality parameters of modified concrete based on low-carbon binders CEM II/B-M 32,5 R, CEM IV/B 32,5 R, CEM V/A 32,5 R, MC 22,5X. Composition of concrete by weight C: FA: CA = 1:1,87:3,6 (cement – 370 kg per 1 m³). For determining workability of fresh concrete mix was measured slump of a compacted concrete cone (under the action of gravitational forces) which equal to 9.5..15.0 cm. The density of fresh concretes are 2260..2410 kg/m³ and air content amount to 2.6..4.5 %. For the investigated concrete mixes there are no bleeding due to the content of superfine zeolite in the composition of blended cements, because zeolite is characterized by porous structure and a low bleeding than GGBFS, fly ash and limestone. The strength of clinker-efficient concretes is presented in Fig. 6 and the

conformity of the developed concretes based on low-carbon cements to the Cement Industry' road map is shown in fig. 7.

Fig. 6. Strength of clinker-efficient concretes.

Fig. 7. Sustainable concretes based on low-carbon cements.

The possibility of using multicomponent cements in construction technology is largely determined by the properties of mortars based on them. Experimental studies have established the amount of low-carbon binder MC 22.5X for the design of mortar classes M2.5 ... M10. For mortar mixes (consistency by plunger 30-35 mm) water-cement ratio increases from 0.75 to 1.3 with reduction consumption of cement MC 22.5X from 465 to 198 per 1 m³ of sand. The bulk density of masonry mortars varies from 2050 to 1995 kg/m³. As can be seen from Fig. 8, a, class M10 by the compressive strength for masonry mortar is achieved at the consumption of low-carbon binder 465 kg/m³. The consumption of MC 22.5X is 232... 348 kg/m³ to provide the class M2.5...M5. Experimental studies have found that with the using 0.09... 0.18 % Master Air 81 admixture with plasticizing and air-entraining action in the composition of mortars (consumption of MC 22.5X – 465...198 kg/m³, consistency by plunger 30-35 mm) water content is reduced by 10-15 % and bulk density – to 1880...1820 kg/m³. The strength activity index after 28 days increases 1.3-1.1 times, after 90 days – 1.5-1.2 times compared to mortars without Master Air 81 (Fig. 8, b). Modified mortar with a MC 22,5X consumption of 465 kg/m³ is characterized by the highest strength 21.0 MPa.

Consistent efforts with the goal of significant reduction of emissions of CO₂ are directed to research the chemistry of cement that ensures partial or complete replacement of ordinary Portland cement by ecologically

friendly binders [18]. Currently, the consumption of calcium sulphate plasters increases as they belong to the most ecologically friendly binders because of their low energy consumption during the production. Nevertheless, gypsum products have low water resistance. Improved structural and technical qualities of gypsum products, in particular their increased strength and water resistance are ensured by these two methods: the creation of products with low coefficient of water/gypsum or the introduction of Portland cement and active mineral additives to the gypsum binder [19, 209].

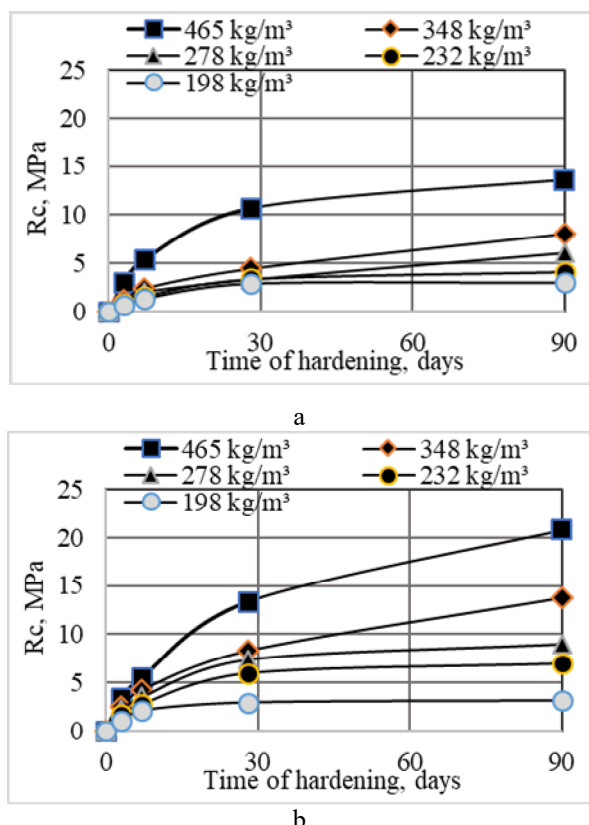

Fig. 8. Compressive strength of mortars based on MC 22,5X: without admixture (a); with Master Air 81 (b).

In gypsum binder, the carbon footprint factor (140.7 kg CO₂/t) is lower by 4.0–6.0 compared to Portland cements. However, the gypsum binder is characterized by a very low (5.0–7.0 MPa) compressive strength and low water resistance. Combining different types of binding substances allows production of strong and water resistance low-carbon dioxide emission composites. The strength of a composite binder based on 75 wt.% G-6 + 25 wt.% MC22.5X in 28 days reaches 20 MPa and in 2.3 times exceeds the strength of building plaster. Due to hardening because of pozzolanic reaction, the strength increases even more and the water resistance corresponds to the hydraulically hardened binders. Simultaneously, the carbon footprint (163.0 kg CO₂/t) of this composite binder is only by 15.8 % higher than one of building plaster, but is significantly lower in comparison to ordinary Portland binder.

The zeolite-based composite plaster binders modified by polycarboxylate's superplasticizers are even more strength and softening coefficient (Fig. 9). They are water

resistant, durable and can be utilized for the production of building mortars, dry mixtures for plaster, restoration works, as well as partitions and walls in wet rooms, for the formation of bulky elements of sanitary cabinets, for devices of self-leveling screeds under a floor.

Fig. 9. Compressive strength (a) and softening coefficient (b) of composite gypsum binders with PCE admixture.

Particularly noteworthy is the use of composite gypsum binder for the manufacture of lightweight concrete – arbolite based on composite binders, organic fillers (up to 50–60 % of the volume) and chemical additives [21]. Blocks using composite binder based on gypsum, cement and superzeolite, as well as hemp as a filler are sustainable, heat resistant, humidity-free – and carbon negative. A hemp houses could be greener, fire-resistant and built quicker than using lightweight expanded clay concrete.

Modified multi-component composite binders containing superfine zeolite and carbonate microfillers can significantly reduce the power consumption during production of various construction materials and decrease carbon footprint, that correspond to the goals of sustainable development in the construction.

4 Conclusions

Development of low-carbon multicomponent cements and modified clinker-efficient concretes and mortars based on them allows to create progressive models of rational use of natural raw materials, fuel, electricity, utilize production wastes, reduce greenhouse gas emissions and solve a number of important environmental, economic and social problems. The urgency of developing the basics of low-carbon cements technologies is in line with the global concept of

sustainable development and life cycle approach with rational use and saving of material and energy resources and is determined by the possibility of reducing CO₂ emissions by 2.5-4.0 times while reducing the content of clinker component.

The compositions of gypsum, Portland cement clinker, pozzolan zeolite-containing components, as well as the use of polycarboxylate superplasticizers allows to produce environmentally friendly modified composite gypsum binders with the increased water resistance. The multicomponent gypsum binders with the preservation of the positive properties of gypsum products and the acquisition of hydraulic properties of Portland cement promotes the development of hydraulic properties, the increase in strength, water resistance and durability of composite gypsum products as a whole. The hempcrete articles based on composite binders are sustainable, heat resistant, humidity-free – and carbon negative.

Modeling the horizontal movement of bulk material in the system “conveyor – rotary mixer”

Vladimir Zaselskiy, Sergey Shved, Mariia Shepelenko, and Nataliia Suslo*

Kryvyi Rih Metallurgical Institute of the National Metallurgical Academy of Ukraine, 5 Stephana Tilhy Str., Kryvyi Rih, 50006, Ukraine

Abstract. In this work, we consider methods for analytical construction of the profile of rotor blades mixer, as well as mathematical modeling of their work on moving and mixing bulk material on a conveyor to increase process efficiency mixing raw materials and optimizing its operating costs. In addition to increasing the effectiveness of the mixing process and lower operating costs, the goal of implementation the proposed methods is the consciousness of production with the least possible errors that would meet modern technical requirements and be adapted to consumer tasks. In this regard, the aim of this work was to determine rational parameters and geometric characteristics of the profile of the rotor mixer blades contributing to improving the quality of mixing the metallurgical charge transported on a conveyor belt. To achieve the goal by modeling, which is a key method of the fourth concept industrial revolution, using the developed mathematical model analyzed the movement of a particle of material along a conveyor belt with its subsequent interaction with the blades of the working body of the rotary mixer.

1 Introduction

To obtain metals and alloys of the required chemical composition and mechanical strength, apply various types of necessary raw materials. Such mixed raw materials, before operations sintering and smelting are called charge materials. Recently, with a deterioration the raw material base of the metallurgical complex of Ukraine, much attention should be paid mixing and other type of equipment capable of existing technological schemes, to improve the quality of preparation of charge materials before sintering and smelting [1], [2]. Implementation the concept of the fourth digital revolution precisely at the mixing stage is promising solution, since such a process is one of the main in technological schemes metallurgical production. Analysis of the works [3], [6], [7] related to the development and improvement of various kinds of continuous mixers in the preparation of bulk materials for their further use shows that such equipment should meet current trends in the development of this kind of technology, namely for metallurgical processes, have high performance and at the same time - the degree of mixing of raw materials with negligible operational and capital costs. However, the improvement of the mixer, made by such a structural scheme, is constrained the lack of theoretical research aimed at studying the movement of material on the blade horizontal mixer installed directly above the conveyor the tape of the transported device. Therefore, the study of the movement of material with blades high-performance mixer, working in conjunction with a layer of conveying raw materials on conveyor belt

is an urgent and timely scientific task. In this paper, we consider methods for analytical construction of the profile of rotor blades mixer, as well as mathematical modeling of the movement of bulk material along them and conveyor belt, which allows, based on technological requirements, to determine the necessary rational equipment parameters that enhance mixing efficiency components of the metallurgical charge. In addition, the purpose of consideration and implementation of such methods is the creation of production with the least number of errors that would ensure the necessary product quality adapted to the needs of consumers.

One such mixer in a number technological schemes of metallurgical production can be used mixer continuous with elastic truss elements, the design of which It is rather well described in a number of works [8-12]. However, an improvement on the mixer, made according to such a constructive scheme, constrained by the lack of theoretical research studies the movement of material on the mixer blades horizontally directed action installed directly above conveyor belt transported devices.

Therefore, the study of motion material with high-performance vanes mixer working in conjunction with the layer conveying raw materials on a conveyor belt, is an urgent and timely task. In this paper, we consider the methods: analytical construction of the profile of the blades charge rotor mixer rotor materials in order to increase the term operating equipment for the existing technological scheme for the production of sinter and pellets; material movement on the shoulder blade horizontal mixer actions.

1.1 Work related sources

The existing rotary mixer with elastic cable elements in [3] has a number of advantages in comparison with batch mixers. They are more effective and can be used in existing technologies without significant investment. However, in [5] a mathematical model was constructed that takes into account additional vibrations that allow the material to move in a state of suspension. This condition allows significantly reduce energy costs during subsequent work, such as mixing.

1.2 Our contribution

This article presents some improvements based on the proposed methodology in [5]. From taking into account additional vibrations, the problem arises of determining the profile of the rotor blades mixer and the interaction of particles of the material with its surface. This article suggested algorithm for constructing the analytical profile of the blade [3] and analysis of the movement of the particle material on its curved surface.

1.3 Work structure

The rest of the paper is organized as follows. Section 2.1 contains preliminary information used in this article that describes the characteristic and principle of operation rotary mixer with elastic elements. Section 2.2 provides a mathematical description. The interaction of the product particles on the surface of the rough profile of the blade when it rotational exit from the material array. Section 2.3 gives an analytical method for determining allowable sector of the process of particle slip. Finally, Section 3 concludes and presents direction for future research.

2 Background

2.1 Rotary mixer design

This type of mixer is shown in Figure 1, for clarity, a section of the front part is made rotary mixer. The principle of this mixer with its design features it is rather well described in a number of works [3], [4], [5]. However, not one of them contains an analysis. the movement of material on the mixer blades, which would have a better idea of him work, and, accordingly, use in those or other technological lines with preparation of metallurgical raw materials production.

Rotary mixer is installed directly to the conveyor belt frame. It consists of a welded frame 1, sections 2. In bearing support 3 of each section two rotors are installed. Rotor drive with flexible cable elements 4 carried out by electric motors 5 sousing V-belt transmission 6. Composite side with V-belt drives 7 are given in blade rotor movement 8. As sealing section applied lamellar rubber 9 and 10. At the inlet and outlet of the mixer A sealing rubber curtain is installed on the end walls. Support and regulation the gap between the tape and the rotors is adjusting screws 11. Side walls sections are closed by fences 12 and 13 in order to prevent injury from

rotating parts. Depending on the technology requirements, number of section scan increase or decrease [3].

The principle of operation of a rotary mixer with a flexible cable rotor next: loose material moving on a conveyor belt, enters the mixing zone (which located between the conveyor belt and working elements of the rotor), where it falls under the effect of complex force 4 in rotor with flexible cable elements each section 2 located first on the direction of movement of the conveyor belt and driven by an electric motor 5. Rotating rotor 4 with its flexible elements that are staggered order for complete overlap of the zone mixing performs integrated impact on the material while loosening and stirring it. Having the ability to change lengths of flexible cable elements, as well as their diameter, can fit rotor with flexible elements for specific conditions technological process. Moving on the material is affected by the blade rotor 8, which performs more than intensive mixing loosened material.

Fig. 1. Rotary mixer with flexible cable element in section [3].

Clearance between work items rotors 4, 8 and conveyor belt supported thanks to the adjusting screws 11. This the gap reduces wear on the tape conveyor belt from abrasive friction material on the tape, thereby increasing its life service. The disadvantage of the mixer in questions that he is not standalone and used with conveyor when transporting dry materials.

2.2 Bulk product behavior on rough profile surface blades during its rotational withdrawal from product array

Consider the motion of a material particle along rough surface of a rotating blade mixer.

We assume that when the blade leaves an array of bulk material that moves along the conveyor belt, she as a result of it excavation carries away some of it portion. Consider the possibility of the process release the scapula from the material, located on it, in the process of rotational rotor movements. We assume that slippage between conveyor belt and rotor blades missing. Then the conditional angular velocity of rotation of the rotor ω_r

with the blades is in kinematic correspondence with the linear speed of the conveyor belt V .

Let the material particle be on the surface of a rotating rough blade (Fig. 2), where h is the height of the layer of transported material on the conveyor belt. To study the movement particles, we introduce two coordinates of the system, as shown in Figure 3. Absolutely one fixed xOy associated with the horizon, and the second τMn movable (relative), associated with the tangent to the profile of the scapula. The tangent axis is inclined at an angle to the radius point position vector.

Fig. 2. Explanation of the interaction of the blade with the transported layer of material (shaping of the blades).

Fig. 3. System of forces applied to material point on the rotor blade making uniform rotation in vertical plane.

The plane of rotation of the blade is located vertically and therefore the action of force gravity per particle in the relative system reference will linearly depend on its angle rotation, from the angle of inclination of the tangent to her profile, as well as from time to time with focus. This dependence may be presented as follows:

$$\begin{cases} G_n = -mg \cdot \cos(\varphi + \theta) \\ G_\tau = -mg \cdot \sin(\varphi + \theta) \end{cases} \quad (1)$$

Note that with uniform rotation of the rotor its current rotation angle is easy to imagine as a function of time:

$$\varphi = \varphi_0 + \omega_e \cdot t \quad (2)$$

And the angle of inclination of the tangent is a function of the position of the point:

$$\theta = \left(\frac{dy_L}{dx_L} \right) \quad (3)$$

where $\frac{dy_L}{dx_L}$ is the derivative of the profile function of the blade, which, in accordance with the solution differential equation (based on Fig. 2, the condition for the formation of the blade profile is accepted in the diametrical plane of the rotor), we obtain the profile function of the blade

$$y(x) = x \cdot \frac{\sqrt{x^2 - (R-h)^2}}{2 \cdot (R-h)} - \frac{R-h}{2} \cdot \ln \ln \left[\frac{x + \sqrt{x^2 - (R-h)^2}}{R-h} \right] \quad (4)$$

or as a result of which we obtain the following expression for determining the angle θ :

$$\frac{dy_L}{dx_L} = \frac{\sqrt{x^2 - (R-h)^2}}{R-h} \quad (5)$$

Considering that with this choice of reference systems $x=\rho$, we get:

$$\theta = \left(\frac{\sqrt{\rho^2 - (R-h)^2}}{R-h} \right) \quad (6)$$

In addition to gravity in the relative system reference to the particle act: inertia force in her portable movement $\overline{P_{in}}$; inertia force from Coriolis acceleration $\overline{F_{cor}}$ (acceleration vector Coriolis directed according to rule Zhukovsky); two forces from imposed bonds – $\overline{R_n}$ (unconditional one-way response kinematic connection) and $\overline{F_k}$ (reaction through Coulon friction).

The force of inertia in a figurative movement is a function of the relative position of the particle

$$|P_{in}| = m \cdot |a_{en}| = m\omega_e^2 \cdot \rho \quad (7)$$

The force of inertia from the action of Coriolis acceleration is a function of its relative speed, and modulo takes value

$$|F_{cor}| = 2m\omega_e \cdot \dot{\rho} \quad (8)$$

Resistance force to particle motion in neglected air.

Coulomb friction force of a particle with coefficient of sliding friction k about the surface of the blade depends on the pressing force, the value of which corresponds exactly support reactions $\overline{R_n}$ unconditional kinematic connection. The balance of power at relative particle equilibrium in according to the scheme of action of forces in normal to the surface of the scapula will take the form:

$$R_n - F_{cor} - G \cdot \cos \cos(\varphi + \theta) = 0 \quad (9)$$

From where we calculate the friction force modulus:

$$|F_k| = k \cdot F_{cor} + k \cdot G_n = k \cdot m \cdot 2\omega_e \cdot \dot{\rho} + k \cdot mg \cdot \cos \left[\omega_e t + \varphi_0 + \arctg \left(\frac{\sqrt{\rho^2 - (R-h)^2}}{R-h} \right) \right] \quad (10)$$

Based on the basic dynamics equation for relative motion of a material point in accordance with the direction of action of forces, shown in the diagram (Fig. 3), we have:

$$m \cdot \ddot{\rho} = P_{in} - F_k - mg \sin \times$$

$$\times \left[\omega_e t + \varphi_0 + \arctg \left(\frac{\sqrt{\rho^2 - (R-h)^2}}{R-h} \right) \right] \quad (11)$$

Or after substituting the input quantities:

$$\begin{aligned} m \cdot \ddot{\rho} = & m \omega_e^2 \cdot \rho - k \cdot m \cdot 2 \omega_e \cdot \dot{\rho} - \\ & - k m g \cdot \cos \left[\omega_e t + \varphi_0 + \arctg \left(\frac{\sqrt{\rho^2 - (R-h)^2}}{R-h} \right) \right] - \\ & - m g \sin \left[\omega_e t + \varphi_0 + \arctg \left(\frac{\sqrt{\rho^2 - (R-h)^2}}{R-h} \right) \right] \end{aligned} \quad (12)$$

where ρ – relative position coordinate particles (its current radius of position); R – maximum rotor radius, or distance between the axis of the rotor and the surface of the tape conveyor belt; h – the height of the layer of bulk product on conveyor belt; $\omega_e = \frac{V}{R}$ – angular rotation speed rotor with blades; V – speed of movement conveyor belt with material on it; k – coefficient particle sliding friction on the surface shoulder blades; m – particle mass; g – acceleration free fall.

Thus, the differential equation the process of particle sliding along a curved blade surfaces in a certain sector of angles. The rotation of the scapula is formulated. Remains to find out in which sector of the situation blades this process takes place.

2.3 Valid process sector particle slip

Expression (12) contains the initial angle φ_0 installation of the blade on the surface of which begins to slip particles of material. Obviously, with such an initial angle it is advisable to assign an angular position blades at the moment of its end point exit from an array of material as shown in (Figure 4).

Fig. 4. Towards a process sector definition particles sliding along the surface of the scapula.

But in this case, the value of the initial angle in which begins the process of sliding particles on the surface of the blade at the accepted beginning angular position will be half of the reference angle taken with a negative sign:

$$\varphi_0 = -0.5\alpha_0 \quad (13)$$

In the process of sliding particles on the surface blades when it rotates around the axis of the rotor it is necessary to determine the maximum permissible rotation angle value φ_{cr} . This criteria the angle is determined by the safe ejection condition the last particle from the surface of the scapula. Absolute speed direction particles after its discharge from the scapula should not facilitate the fall of the particle to the surface subsequent rotor blades. Based on this conditions take the value of the criteria angle equal to zero:

$$\varphi_{cr} = 0 \quad (14)$$

Using boundary constraints (13) and (14), it becomes possible to analysis on the result of the decision differential equation (12) with the goal selection of device geometry and its modes movement. Investigation of particle slip along the surface of the blade is made for the sector blade position determined inequality:

$$\varphi_0 \leq \varphi \leq \varphi_{cr} \quad (15)$$

Outside the range (15), the slip process itself slow last particle over the surface the blades will be considered unacceptable.

Place on the working surface of the scapula several particles on equal radial distances from each other and analyze the process of their sliding on the surface of the blade in according to inequality (15).

Solution of the differential equation (12) we will carry out for each of the selected particles by numerical methods.

When illustrating the results, we will take into account the uniformity of rotation of the rotor with shoulder blades by law:

$$\varphi(t) = \varphi_0 + \omega_e \cdot t = \varphi_0 + \frac{V}{R} \cdot t \quad (16)$$

in the valid range:

$$-0.5\alpha_0 \leq \varphi \leq 0 \quad (17)$$

For calculations, we'll use the program written in accordance with equation (12) and (17). The calculation results are shown in Figure 5 for the following basic parameters:

- the number of particles on the blade in uniform radial distribution – 5;
- the outer radius of the rotor with blades is 1 m;
- the coefficient of friction the surface of the scapula is 0.4.

We accept the value of independent variables parameters:

- the speed of the conveyor belt with an array material – 10 m/s;
- coefficient of fineness of the rotor with blades (the ratio of the height of the layer of material to the outer the radius of the rotor with blades) – 0.2 (such thus, in this case, the height of the layer of material 200 mm).

The radius of the initial position of the point increases with an increase in its index. Point zero index in the initial position located in the area of the rotor hub with blades.

Fig. 5. The selected parameters of the variables fully support unloading.

Selected variable parameters fully support unloading the angle of rotation of the blade, corresponding condition (15) looks like a rectangle φ_{cr} , bounded by a corner to the right and a radius from above R . If upon reaching the blade criterion angle φ_{cr} is the slowest particle on the blade (with a zero index) it did not leave, those did not reach the radius R , then this means that some slow particles in the process rotor rotations with blades do not toss in the direction of movement of the conveyor.

These particles fly out in such a way that again rotor traps and fall into the entry area blades into an array of material. Thus, the criterion of appropriateness and device efficiency meets the case when all the curves leave the rectangular region without crossing its right border.

After separation of the particles of bulk material from the surface of the scapula, it starts loose flight in the air under the action of acquired kinetic energy. Separation of each particle happens at a specific time when reaching a certain the current angle of the blade (Figure 6).

Fig. 6. On the determination of the particle velocity vector when it is separated from the scapula.

On the determination of the velocity vector particles at its separation from the scapula in accordance with the law of addition of speeds we have the vector equality:

$$\vec{V}_A = \vec{V}_\tau + \vec{V}_\rho \quad (18)$$

where \vec{V}_A – is the vector of absolute particle velocity in the moment of its departure from the surface of the scapula; \vec{V}_τ – vector of radial particle velocity; \vec{V}_ρ – vector of tangent speed particles.

Both vector terms can be calculated in its absolute value from the following ratios:

$$|\vec{V}_\tau| = V \quad (19)$$

$$|\vec{V}_\rho| = \frac{d\rho}{dt} \quad (20)$$

Expression (20) is determined on the basis of the found differential solution equations (12).

In the projection on the axis of the absolute coordinates xOy with taking into account the negativity of the angle φ , equality (18) will take the form:

$$\begin{cases} V_{Ax} = -V \sin \varphi + V_\rho \cos \varphi \\ V_{Ay} = V \cos \varphi + V_\rho \sin \varphi \end{cases} \quad (21)$$

After determining the projections of the absolute particle velocities and taking into account the angular position blades solve the differential equation movements of each particle and find for each of them the law of motion before they fall on material surface.

$$\begin{cases} x = \int V_{Ax} dt + C_x \\ y = \int V_{Ay} dt + C_y \end{cases} \quad (22)$$

Integration constants are determined by initial conditions at the initial moment time:

$$\begin{cases} x(0) = R \cdot \cos \varphi \\ y(0) = R \cdot \sin \varphi \end{cases} \quad (23)$$

The distance from the axis of the rotor to the place of impact of each particle at time T along the surface material on the conveyor is determined:

$$L = x(T) \quad (24)$$

In this case, the vertical coordinate of all the fallen particles will be the equal

$$y(T) = h - R \quad (25)$$

Thus, the definition of longitudinal surface area material moving along with the conveyor belt ribbon can be considered defined.

An example of calculating the sieving zone with the previous initial conditions of movement of the rotor and belt the conveyor is shown in Figure 7.

From the obtained dependencies and, accordingly, Figure 7 scattering parts, we can conclude that effective material excavation will depend heavily on geometric dimensions of the wheel, speed transporting material and its height to conveyor belt, as well as physical mechanical properties of the processed product characterized by a coefficient of friction slip.

Fig. 7. Particle scattering with one blade for a given rotor.

3 Conclusion

The paper presents a mathematical model, which allows us to analyze the material's movement – “conveyor-mixer” systems and choose its rational parameters, promoting homogeneity of raw materials used in various technological metallurgical production processes.

Kryvyi Rih National University, Ferrous metals metallurgy & foundry Department, Ukraine

Abstract. In order to ensure sustainable development of rolling production, technological processes were investigated using computer simulation, which allows us to examine a large amount of information regarding modes of reduction and energy consumption of metal treatment under pressure in order to determine rational values. Simulation of hot rolling process using DEFORM-3D software was performed to investigate energy parameters of treatment and to determine rational reduction modes. During investigation, objects were located in space, exact positioning of casting rollers respectively to workpiece was performed, and rheological model of deformable material was specified, where rigid-plastic environment was adopted. Mechanical properties of workpiece material were determined, low carbon steel was selected as material, reduction between casting rollers was specified, and friction coefficient between workpiece and rollers, which is equal to 0.3; contact interaction between casting rollers and workpiece was specified, hot rolling temperature was set to 1000°C. Finite element model of treated material was developed, displacement in deformation zone during hot rolling and vector field of metal movement were determined. Changes in force during treatment, deformation stress during rolling were determined. Changes of rolling force in deformation zone in course of time were determined. Distribution of active stress in deformation zone was investigated. Investigations allowed us to determine energy consumption of rolling process depending on reduction modes, which provided rational treatment modes.

1 Introduction

In recent years, scientists of the Ferrous metals metallurgy and foundry Department of Kryvyi Rih National University have studied such important and relevant areas: the impact of the electric field on the steel and cast iron structure during the pouring of the alloy into the mold: the study of processes in the deformation zones during the longitudinal rolling of steel billets.

Sustainable development of steelmaking production is impossible without detailed research and improvement of technological processes of rolling, which require high energy consumption. Recently, active development of informational technologies has made possible their widespread usage in development of metal treatment under pressure processes, which allows to solve problem of increasing of rolling production efficiency and ensure production of competitive products with required quality and with minimal energy consumption. Task to improve rolling technology using rational reduction modes, which provide required quality of products with minimum energy consumption is relevant. For this purpose, it is necessary to carry out research of metal treatment using DEFORM 3D computer software, which significantly speeds up treatment process improvement.

2 Literature review and problem definition

Development of technological processes of metal treatment under pressure processes to ensure sustainable development of industry and society requires solving of large number of complex problems. Main purpose of development and improving of rolling technologies is to identify regularities of process, significant factors and parameters that affect its quality, to evaluate possible effect of reduction parameters to operational properties of produced products, to energy consumption during production [1, 2]. During rolling process, deformation zone is formed, which in is given much attention in theory of metal treatment under pressure because complex deformation processes take place in it, which further affect product quality and energy consumption of process. Investigations have shown that complex stress-strained state [3, 4] appears in deformation zone, which shall be taken into account during designing and improvement of technological processes, which is very difficult to investigate in manufacturing environment. During investigation of reduction processes using computer program, obtained data allowed us to develop informational field of technological processes of rolling, and thus provides ability to control both process and

* Corresponding author: victoria_4@rambler.ru

properties of products. Computer simulation provides opportunity to obtain large amount of information, to conduct comprehensive investigation of rolling process, to determine its features, to consider and to compare large number of alternative technological processes. Currently, analytical energy method of power balance and finite elements analysis have been acquired to investigate bulk deformation processes during metal treatment under pressure. A lot of investigations were executed regarding defect formation problem during pressing using finite elements analysis [5, 6], but it shall be noted that hot rolling process of thick sheets is not investigated in this work. Currently, promising results are given by simulation modeling of bulk deformation processes using finite elements analysis [7], which is most common numerical method for solving technological tasks.

Computer software DEFORM 3D, which is designed to analyze complex three-dimensional processes of plastic deformation of metal while its reduction, has great potential in this respect. This program is finite element simulation system [1, 8] and one of leading design-grid methods that can be finally adapted to plastic deformation tasks solving. Simulation of rolling processes using DEFORM 3D has developed more rational technologies with significantly reduced time for their design [8]. Software [9, 10] was used for research of sheets hot rolling for analysis of three-dimensional metal flow during treatment, nature of metal forming was predicted, microstructure of products was obtained, deformation force was minimized, number of transformations was optimized, but energy consumption for process was not determined.

Therefore, there is reason to believe that insufficient attention is paid to distribution of rolling force and energy consumption for process during hot rolling simulating of thick sheets using DEFORM 3D.

3 Purpose and tasks of research

Purpose of this work is to investigate energypower parameters of hot-rolling process of thick sheets, using computer software DEFORM 3D for simulation, which will provide evaluation of rational treatment modes.

To achieve this goal, following tasks were set:

- to analyze possibilities of using finite elements analysis for studying processes of metal treatment under pressure;
- to develop model of hot rolling to study effect of rolling force on physical and mechanical characteristics of treated material;
- to determine energy consumption and rational reduction modes during process of hot rolling of thick sheets.

4 Data and methods

4.1 Initial data for investigation of hot rolling of thick sheets

Technology of thick strips production by hot rolling was used to determine rational technological parameters that will ensure sustainable development of industry. Initial

data for simulation [11]: dimensions of initial billet – height h_0 varied from 300 to 500 mm; width b_0 remained constant and equaled 1000 mm; length $l_0 = 1000$ mm; Δh of their reduction varied from 30 to 100 mm; initial rolling speed v_0 varied from 3 to 10 m/s; radius of rollers $R_B = 400$. Rolling temperature was 1000°C. Low carbon steel was used as treated material.

4.2 Methodology of investigation of energypower parameters of thick sheets hot rolling

Model of hot rolling of thick sheets using computer software DEFORM 3D was built to determine rational reduction modes.

During simulation Perzyna's model was used [10]:

$$\dot{\epsilon} = \gamma(\dot{\epsilon}/S - 1)^m, \quad (1)$$

where γ – fluidity; $\dot{\epsilon}$ – effective stress; S – flow stress; m – material parameter; $\dot{\epsilon}$ – effective strain rate.

In this method creep will not occur until effective stress exceeds the yield strength of material. If effective stress is less than the flow stress, the resulting strain rate is zero.

Yield strength of material was set according to energy law [10]:

$$\sigma = \epsilon^n \cdot u^m + y, \quad (2)$$

where σ is effective stress of plastic material flow, ϵ is material deformation, u is material deformation speed; n is deformation degree indicator, m is indicator of deformation degree speed, and y is material constant.

Deformation process was studied at the beginning of rolling process: with help of computer program, objects were placed in space, distance between rollers was determined taking into account dimensions of workpiece and reduction value (Fig. 1), and rheological model of deformable material was identified, where rigid-plastic environment was adopted. While simulation, flexible model was used for workpiece, and rigid material model was selected for rollers. Behavior of workpiece material was described using diagram “Stress-Strain”. Mechanical properties of workpiece material were determined, low carbon steel was selected as material, reduction between rollers was specified, and coefficient of friction between workpiece and rollers is equal to 0.3; contact interaction between roller and workpiece was specified, hot rolling temperature was set to 1000°C, deformation speed, identified at the beginning of treatment, was 3 mm/s.

Deformation process was divided by 90 steps.

Number of steps was determined from formulas [9, 10]:

$$n = x/(v\Delta t), \quad (3)$$

where n is number of steps, x is summary movement of main roller, v – main roller speed, Δt is time increment for one step.

In order to divide workpiece into finite elements, grid was generated where 80,000 elements were specified (Fig. 2). Automatic grid generation mode was used during investigation.

Fig. 1. Scheme of rollers and treated material location.

Fig. 2. Finite element model of treated material.

Scheme (Fig. 2) shows that during simulation process, workpiece having 1.37×10^3 points and 5.62×10^3 elements was obtained.

For exact location of objects, mutual positioning of rollers and workpiece was performed, as shown in Fig. 3, a and b, where continuous interaction of rollers and workpiece side and back is observed.

Material of treated workpiece was determined from computer software library. AISI-1015_(20-1200C)

carbon steel material was used for investigation. The properties of the material are learned in many ways. Material is easy to deform. The material has elastic and plastic properties.

a

b

Fig. 3. Positioning of objects: a) side view; b) back view.

Elastic properties of material were determined (Young's modulus and Poisson's ratio), which equal to 0.3 and $1.5 \cdot 10^5$ accordingly, which are constant values. Diagram "Flow Stress-Strain" is presented in Fig. 4, which shows that if strain during reduction increases, flow stress increases as well.

Parameter "Strain" shows degree of workpiece relative reduction, which is determined according to

formula [11]:

$$\varepsilon = \Delta h / h_0, \quad (4)$$

where Δh is absolute reduction,

$$\Delta h = h_0 - h_1 \quad (5)$$

where h_0 , h_1 – initial and final thickness of strip accordingly.

Fig. 4. Diagram “Flow Stress-Strain”.

Fig. 5. Thermal conductivity depending on temperature.

Thermal conductivity of material, and its dependence on temperature is shown in Fig. 5, where it is shown that with increasing temperature, thermal conductivity

decreases until temperature reaches 800°C. During further heating thermal conductivity increases until temperature reaches 1000°C, after this temperature thermal conductivity decreases again. So, treatment is carried out under conditions of maximum thermal conductivity.

Heat capacity of investigated material, which depends on treatment temperature, was determined (Fig. 6). Graph shows that heat capacity of treated steel at temperature of 700°C takes maximum values. At treatment temperature of 1000°C, heat capacity decreases.

Fig. 6. Dependence of heat capacity of steel on temperature.

Thus, model of hot rolling of thick sheets was constructed to investigate processes occurring in deformation zone.

5 Results of investigation of energypower parameters of hot rolling of thick sheets

Investigation of deformation distribution in treated material enabled to identify its displacement during reduction (Fig. 7). Figure shows distance of displacement and its distribution in deformation zone.

Material flow along curvature of coordinate grid can be seen on Fig. 8, which shows that maximum deviation from original location occurred in center of deformation zone with upper layers.

Vector field of metal displacement during deformation was investigated (Fig. 9), which shows metal movement direction during reduction and displacement of grid points. During simulation process, graph of deformation force change in course of time is made, where it can be seen that force increases from zero to 6.68 MPa during first 27 s. After this, force slowly increases to 8.35 MPa and displacement of metal varies from 1.34 to 25.2 mm.

During simulation process, graph of deformation force change in course of time is made, where it can be seen that force increases from zero to 6.68 MPa during first 27 s.

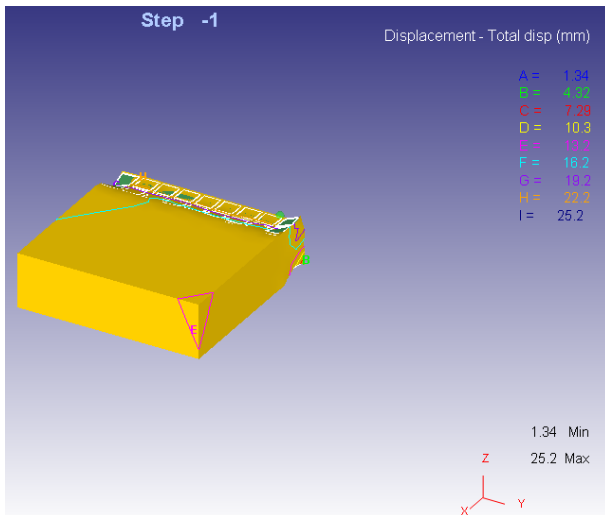

Fig. 7. Metal displacement in deformation zone during reduction.

Fig. 8. Coordinate grid of billet.

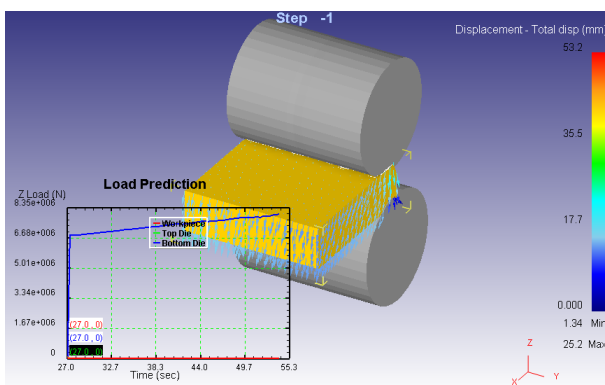

Fig. 9. Vector field of metal displacement during deformation.

After this, force slowly increases to 8.35 MPa and displacement of metal varies from 1.34 to 25.2 mm.

Figure 10 shows graph of change of force applied on roller at initial rolling moment, where it can be seen that force applied on roller varies from 0 to 4.1 MN and displacement fields apply up to 27 mm. Under real

conditions for these modes, rolling force reached 4.4 MN [11], which corresponds to high simulation accuracy, where error is 6%.

Fig. 10. Change of force applied on roller.

During treatment under pressure, treated material is subjected to non-uniform stress that causes non-uniform plastic deformation. It is determined that both circumferential and normal stress occur during rolling.

Change of stress during deformation was investigated (Fig. 11). It is found out that during hot rolling, large reduction, which reaches more than 10 mm, reduce effect of stress non-uniformity on product quality.

Fig. 11. Change of stress during deformation.

Distribution of acting stress according to its value is shown in Fig. 12, where it is seen that its value in deformation zone reaches 37 MPa and decreases with decreasing reduction value.

6 Discussion of energypower parameters investigation results and identification of rational reduction modes

Thus, deformation and energy parameters of hot rolling were investigated by finite element simulation of processes in DEFORM 3D complex. Developed model takes into account direction of metal displacement during rolling, change of force during reduction in deformation zone, distribution of acting stress and its change. Such investigations allowed to develop technological scheme which usage enables to increase accuracy and to improve

internal structure of metal products at rational energy consumption.

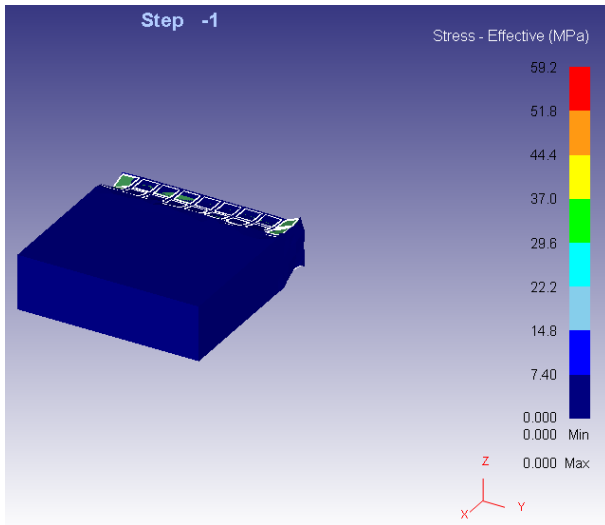

Fig. 12. Distribution of acting stress in deformation zone.

Investigations enabled to identify energy consumption for rolling process depending on reduction modes, what enabled rational treatment modes.

Energy consumption includes kinetic energy of rolled workpiece, potential energy in deformation zone for surface tension formation and metal strengthening, strain energy and energy for metal heating [11].

Kinetic energy of rolled workpiece was determined according to formula [11]:

$$E_k = 0,5 \rho b_1 h_1 v_1^3, \quad (6)$$

where v_1 – roller speed; b_1 – width of strip after rolling; ρ – steel density, $\rho = 6860 \text{ kg/m}^3$.

Potential energy consumption in deformation zone for surface tension formation and metal strengthening are determined according to formula:

$$E_p = 2b_1 h_1 v_1 \sigma_{st} + V \sigma_T / \tau, \quad (7)$$

where V – deformation zone volume; m^3 ; σ_{st} – surface tension; τ – duration of metal being in deformation zone; σ_T – yield strength.

Strain energy:

$$A = \sigma_T (\varepsilon_h + \varepsilon_b + \varepsilon_l) h_1 b_1 R / \tau, \quad (8)$$

where R – rollers radius, ε_h ; ε_b ; ε_l – relative deformation of sheet during reduction, broadening and elongation.

Energy consumption per unit of time for heating of rolled products

$$Q = V \sigma_T i / \tau, \quad (9)$$

where i – heat capacity.

To determine total energy consumption per unit of time, sum of listed items was calculated.

$$W = E_k + E_p + A + Q \quad (11)$$

Investigation results are shown in Table 1.

Table 1. Energy-power parameters of hot rolling process.

h_0 , mm	h_1 , mm	b_1 , mm	v_1 , m/s	W , kJ/s
300	255	1150	5,12	878474,2
500	400	1200	3,2	10144297

Such investigations enabled to use rational reduction modes (Table 1) during development of technological process of thick sheets manufacturing by hot rolling, which ensures sustainable development of rolling technologies.

7 Conclusions

During execution of investigation on hot rolling process of thick sheets, following results were obtained:

- opportunity to use finite elements analysis for investigation on processes of metal treatment under pressure was analyzed, that enabled execution of investigation on hot rolling process of thick sheets using computer software DEFORM 3D;
- model of hot rolling process that enables to investigate physical and mechanical processes in deformation zone, which occur during metal treatment under pressure was developed;
- deformation force and its distribution in deformation zone were identified; energy consumption and rational reduction modes during hot rolling of thick sheets that enable manufacturing of high-quality products were specified;
- it is suggested to use rolling modes adopted in Table 1 during manufacture of thick sheets to save 6-8% of energy during plate rolling

Analysis and synthesis of factors determining the sintering speed of sinter charge

Serhii Saveliev*, and Mariia Kondratenko

Kryvyi Rih National University, Ferrous metals metallurgy & foundry Department, Kryvyi Rih, Ukraine

Abstract. The main objectives of the study are the analysis and generalization of the parameters that determine the intensity of the sintering, the development of a model of motion of the combustion zone of the sinter charge. As a result of the analysis of the known indicators of the intensity of the sintering process, it was shown that the most representative characteristic of the intensity of the process is the vertical sintering speed, which is an integral part of the complex intensity indicator – the specific productivity of the sintering machine. Many various models of the sintering process have been developed. The author develops a new mathematical model of the motion of the solid fuel combustion zone during sintering of the sinter charge (vertical sintering speed). The model is presented in the form of an expanding network of separate interrelated dependencies (equations), selected as independent submodels. The results of the study using the developed model of the dependence of the vertical sintering speed on the solid fuel content and on the flux content in the charge, are presented. It is concluded that the presented model can be considered as an element of a universal model software complex of the sintering process.

1 Introduction

At the present stage of development of ferrous metallurgy, sinter is and will remain for a long time the main type of prepared iron ore for the production of pig iron and pig iron, in turn, is the main source material for steel production. Therefore, issues related to improving the efficiency of sinter production are of undoubted practical and scientific interest, are one of the conditions for ensuring a sustainable future for the steel industry. One of the urgent problems of scientific and technological progress in sintering production is to increase its intensity, which means increasing the intensity of the technological process, increasing its speed.

Despite the presence of a rather large number of monographs, articles, scientific and technical conferences devoted to the intensification of the sintering process [1-3], methods for assessing and indicators of the intensity of the sintering process are not well understood. To date, a detailed analysis of the used indicators of the intensity of the sintering has not been performed, the relationships between them have not been studied, as is done, for example, with respect to the indicators of the intensity of the blast furnace. This situation negatively affects the development of sintering production, since it does not allow a reliable comparison of the intensity of the sintering machines, the sintering rate of sinter charge as well as the development effectiveness of various methods of intensifying the sintering process of the iron ore charge, and the assessment of the reserves for improving the technical and economic indicators of the operation of

sinter plants. Since the determining technological operation in the production of sinter is the sintering of the sinter charge, it is precisely on it, in the first place, attention should be paid to solving this problem. This article is devoted to the analytical study and generalization of indicators of the intensity of the sinter process, factors affecting the of a new mathematical model, the movement of the combustion zone of solid fuel of the sinter mixture and its application to assess the influence of various factors on the sintering.

2 Literature review

The analysis of indicators of the intensity of the sintering process should begin with the term “intensity of the sintering process” proposed by H. Wendeborne in 1934. It is defined as the ratio of the total heat consumption for heating a material to the amount of heat released during the combustion of carbon in CO and CO₂ and during exothermic reactions, minus the heat for oxide dissociation and evaporation water, the value of which is close to 1.9-2.1, is essentially a thermal characteristic of the sintering process, depending on the composition of the charge. This indicator is not related to the speed of the sintering process and is not used to assess the intensity of the sintering process.

As a rule [4, p. 50; 5, p. 345], the sinter process intensity (sinter machine operation intensity) is estimated using two indicators: 1) specific sinter productivity, measured in tons of suitable sinter, produced from 1 m² of sintering area of the sinter machine in the “hot” hour (that is, without taking into account the downtime of the sinter

* Corresponding author: comher@bk.ru

machine); 2) the vertical sintering speed, measured by the length of the path traveled by the combustion zone of solid fuel per unit time.

A feature of the sintering process, which must be taken into account when assessing its intensity, is the complex nature of the process, which includes three successive technological stages: 1) preparation of the charge for sintering; 2) sintering of the charge; 3) crushing sinter and separation of the return. Each of the stages has both a direct effect on the intensity of the sintering process, and indirectly – through the impact on the subsequent technological stages of sinter production. Based on these considerations, the specific productivity of the sinter machine is a comprehensive indicator of the overall intensity of the sintering process, since all the above stages of the technology of sintering production find expression in it. It is also obvious that the vertical sintering speed directly characterizes only the second stage of the sintering technology and should be considered as one of the components of the overall intensity of the sintering process. The two other components that determine the overall sintering intensity should be considered the bulk mass of the charge and the yield of suitable sinter from the charge, which directly characterize the first and third stages of sintering – preparation of the charge for sintering, crushing of sinter and separation from it the return respectively.

We derive a formula relating the general indicator of the intensity of the agglomeration and the private (its components) indicators of intensity. To do this, we will use the following notation: q_s – specific productivity of the sinter process according to suitable sinter, kg/(m² s); ρ – bulk density of the charge, kg/m³; v – vertical sintering speed, m/s; k – yield of suitable sinter from the charge, a fraction of units; then the general indicator of intensity will be a product of its three private components:

$$q_s = \rho \cdot v \cdot k. \quad (1)$$

Comparison of the three components of the total (complex) indicator of the intensity sintering shows that the most significant and important of them is the vertical sintering speed. The predominant role of the vertical sintering rate in the overall intensity of the sinter process is due to at least three circumstances. Firstly, it is the only component of the general intensity, which has a unit of time in its dimension, without which the concept of intensity loses its physical meaning. Secondly, the practical possibility of sintering intensification is associated, first of all, with an increase in the vertical sintering speed, which in real conditions of sintering production varies widely. The increase in the intensity of the sinter process due to two other components is in most cases limited by the relatively insignificant effect of the composition of the initial charge materials on the bulk density of the charge, as well as the requirements for the quality of the finished sinter. Thirdly, the vertical sintering speed characterizes the process of burning solid fuel of sinter charge, which is the cause of the formation of the melt, which actually ensures the sintering of the charge during the sintering process.

Given the importance of the indicator of the vertical sintering speed of the sinter charge, the practical and theoretical interest is the problem of its calculation definition, for the solution of which today there is no reliable generally accepted technique.

With sufficient accuracy for engineering calculations proposed [6, p. 496] assume that

$$v_s = w_o / (V_g \cdot \rho), \quad (2)$$

where v_s – vertical sintering speed, m/s;

w_o – gas filtration rate in the layer, m/s;

V_g – specific yield of sinter gas, m³/kg dry charge;

ρ – bulk mass of the sinter charge, kg/m³.

At the same time, it is known [6, p. 507] that the vertical sintering speed is directly proportional to the gas permeability of the sintered layer R , m³/m² min, the heat capacity of gases c_g and inversely proportional to the apparent heat capacity of the charge $c_{ap.ch.}$:

$$v_s = k (c_g / c_{ap.ch.}) R, \quad (3)$$

where k – coefficient of proportionality.

Comparative calculations have established that formula (2) has the greatest versatility and suitability for practical use. Formula (3) is less preferable for the calculated determination of the vertical sintering speed due to the difficulty of accurately taking into account all the factors affecting the apparent heat capacity of the charge and the ambiguity of its determination methods. Moreover, comparing formulas (2) and (3), it should be borne in mind that in the region of a high carbon content in the charge (more than 4%), despite the decrease in the apparent heat capacity of the charge due to an increase in the mass fraction of carbon in it, the sintering rate decreases [5, p. 170], although according to formula (3) it should increase.

Another indicator characterizing the intensity of sintering of the charge may be the residence time of the charge on the sinter machine (more precisely, over the sintering area of the sinter machine). If we denote the height of the sintering layer of the mixture through H (m), then in the normal course of the sinter machine, the residence time of the charge on it is determined by the formula

$$\tau = H / v. \quad (4)$$

Substituting into the formula (1) instead of the vertical sintering speed its value from formula (4), we obtain a slightly different, more convenient for practical use form of the formula for calculating the specific productivity

$$q_s = \rho \cdot H \cdot k / \tau. \quad (5)$$

The main method of theoretical generalization of factors influencing any process is mathematical modeling, which is widely used in various fields, including in the process of agglomeration. Modeling of sintering and firing processes should contain a combination of the most important properties inherent in the objects of study. When constructing models of sintering and firing, it is necessary to take into account the numerous parameters of this process [7]. Important input parameters are: the

content of the main components in the charge; charge moisture; gas permeability of the charge; charge layer height; air consumption for the process; ignition conditions – hearth temperature (temperature in the space of furnace), ignition temperature (temperature above the surface of the sintered charge), generalized heat treatment temperature. Important output parameters are: sintering speed; composition and temperature of exhaust gases; mass fraction of iron oxide in the finished product; discharge; sintering time. Disturbing effects: change in the composition of the charge; change in the moisture content of the charge; change in the degree of compaction of the charge; change in the height of the charge layer; change in the speed of movement of the sinter; suction of cold air; change in discharge above the ignited layer; change in the fuel-air ratio.

Currently, computer simulation has become widespread, making it possible to process large amounts of information as part of control systems for complex metallurgical processes, which is sinter production. It is believed [8] that the combination of a mathematical model and artificial intelligence is a suitable method for controlling the sintering process.

Deficiencies and limitations of existing mathematical models for determining the performance of sintering machines were identified [9]. These disadvantages depend on a number of technological factors, often interrelated: the speed of movement of the trolleys of the sintering machine, the vertical speed of sintering of the charge, the speed of filtration of air in the layer of the sinter charge. Based on the identified shortcomings and limitations of the existing mathematical models for calculating the performance of sintering machines, the following basic set of technological factors was proposed to develop a mathematical description of the dependence of the performance of the sintering machine on the parameters of the sintering process: general gas-dynamic resistance of the charge layer; the height of the charge layer on the sinter machine; bulk density of the sinter charge; particle size distribution of the sinter charge (the size of the sintered material expressed in terms of the equivalent diameter of the pelletized charge); the duration of the sintering of the charge; sinter charge temperature; sinter charge moisture; return share/yield; carbon content in the sinter charge; the content of fine-grained concentrates in the sinter charge.

A study of the performance indicators of the agglomeration process [10] showed that in laboratory conditions the most objective is a comparative assessment of the productivity of the sinter process by raw charge and yield of sinter with a closed balanced cycle of the return of the constant size. Under production conditions, it is advisable to conduct a comparative assessment of the specific productivity of the sinter process taking into account the total yield of the return or the strength of the sinter.

Based on the characteristics of the sintering process, a long and short term control strategy of sintering burn through point was put forward [11], with the burn through point optimized with a fuzzy bed controller. Long term control was realized by adjusting bed height or density according to the state of preignition permeability and vertical

sintering speed. The rising position of gas temperature was stabilized by adjustment of pallet speed, enabling short term control to be carried out. By using vertical sintering speed to represent bed permeability a prediction model of vertical sintering speed was established. The predicted results are in accordance with calculated values and accuracy of the model is >95 %. The application of system shows that the accuracy of guidance is >95 % and this system can be used to industry production.

Using the dimensional analysis method, formulas (models) for the efficiency of the sintering process (specific productivity of the sintering machine) were developed from: 1) the gas permeability of the charge; 2) the size of the charge; 3) a specific load complex equal to the product of the height of the charge layer by the bulk density of the charge; 4) vertical sintering speed [12]. These formulas allow us to calculate the optimal process parameters for specific charge conditions of the sintering process.

The above analysis shows that the intensity of the sintering process (vertical sintering speed) is determined by a combination of factors forming the material composition and structural and gas-dynamic characteristics of the sintered charge layer. Based on this approach, we will carry out mathematical modeling of the process of moving the combustion zone of solid fuel in the sintered layer, taking as a basis formula (2), as the most versatile and suitable for practical use.

3 Problem formulation

Based on the foregoing material, the following tasks were set in the work. To develop a new model of the movement of the combustion zone of solid fuel of the sinter charge, characterizing the intensity of the sintering process, and also discuss the possibilities of its application to assess the influence of various factors on the sintering intensity.

4 Methods

The following methods were used to solve the tasks:

- scientific analysis and generalization of previously performed studies of agglomeration production aimed at determining the factors that determine the sintering rate of the sintering charge;
- theoretical studies of the influence of individual factors that affect the sintering rate of the sintering charge;
- experimental studies of technological techniques what determines the speed of the combustion zone of solid fuel;
- mathematical modeling of the process of moving the combustion zone in the sintering layer.

5 Analysis

The development of a model for moving the fuel combustion zone in the charge began with the formalization of this process. At the same time, a number of interrelated physical and chemical processes and gas-dynamic phenomena were taken into account when preparing the charge for sintering and directly during

sintering of the sintering charge layer, namely: the formation of the bulk mass of the pelletized charge; gas movement in the sinter layer; burning carbon solid fuel; dissociation of carbonates; the change in gas volume along the height of the sintered layer as a result of heat and mass transfer processes.

The main structural elements of the model are charge parameters and gas parameters that characterize the initial state of the system.

The parameters of the sinter charge, characterizing the initial state of the system, include: the content of the individual components of the charge; mass fraction of carbon in fuel, CaO in limestone and CaO_{act} in lime; fractional composition of fuel and charge; charge layer height.

The input gas parameters established during the calculations for a specific case of sintering are: the

composition of the gas at the entrance to the layer; air suction rate through the sinter layer; specific air consumption for sintering.

The processes under consideration are grouped into the following subsystems: gas filtration rates in the layer; specific output of sinter gas; bulk density of the pelletized charge.

The output parameter is the vertical sintering speed of the sinter charge.

Thus, the structural diagram of a mathematical model can be represented in the form of Figure 1.

Having designated the main structural elements of the model, we will carry out the development and idealization of its mathematical description.

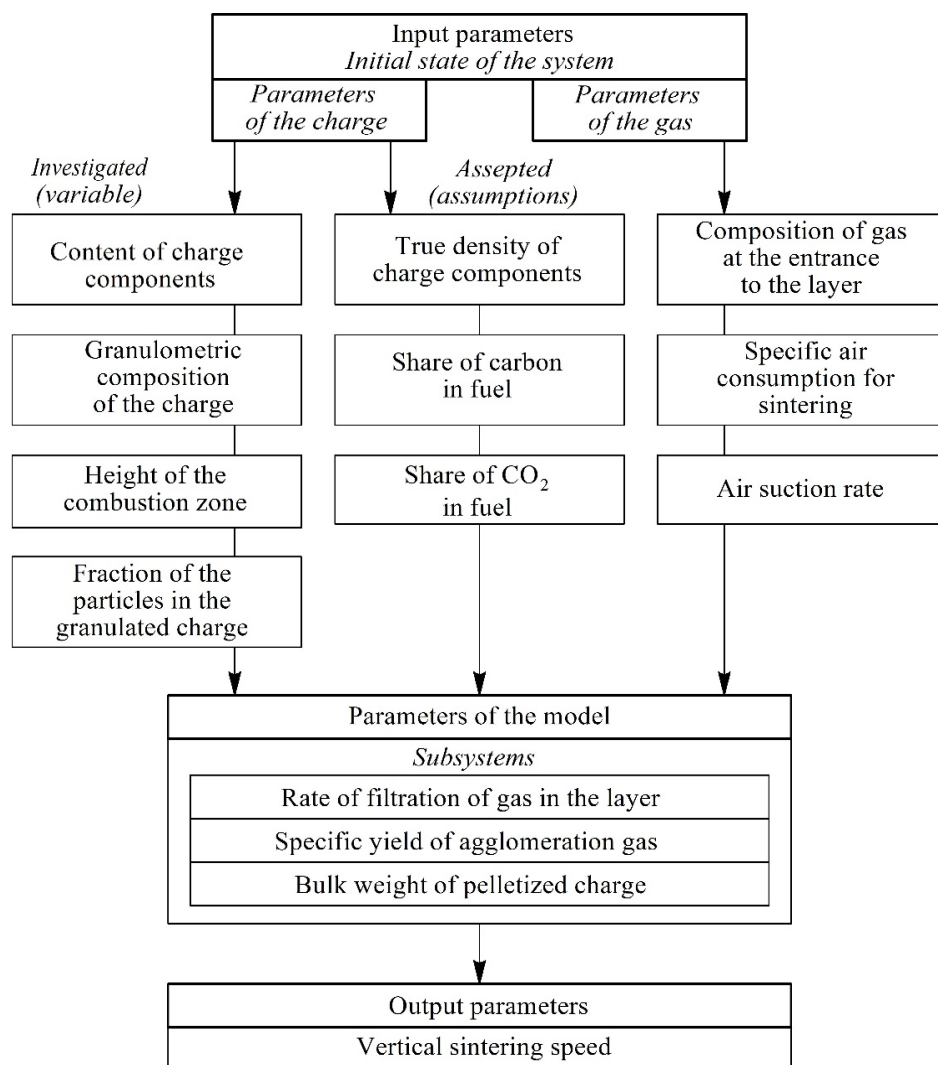

Fig. 1. Structural scheme of mathematical model of movement of the combustion zone solid fuel in the sintering layer of the charge (vertical sintering speed).

In developing the mathematical description of the conceptual model of the vertical sintering speed, the following basic assumptions were made:

1) the charge is presented in the form of ore, fuel, flux particles and the return of spherical shape;

2) carbon burning occurs according to the reactions $\text{C} + 0,5\text{O}_2 = \text{CO}$, $\text{C} + \text{O}_2 = \text{CO}_2$;

3) the granulometric composition of the pelletized charge is determined by the mass fraction of individual fractions of fineness in the initial charge and the content of binder additives under optimal pelletizing conditions;

4) the gas flow is evenly distributed over the cross section of the layer, and its flow rate over time is unchanged;

5) heat loss to the environment is negligible;

6) the rate of combustion of a fuel particle is determined by its size and true density;

7) the fuel burns in a layer of inert materials and its particles are equidistant from each other.

When developing submodels for determining the gas filtration rate, the following assumptions were made:

- the specific air consumption for sintering the non-fluxed charge from hematite ores and magnetite concentrates is 0.35-0.40 m³/kg (in the practice of sintering of iron ore materials in most cases the carbon content does not exceed 5% and the specific air consumption remains almost the same [5, p. 111]). This assumption was made when calculating the specific yield of sinter gas (based on typical air flow);

- the height of the combustion zone for typical sintering conditions (fuel with a size of 0-3 mm) is 1/10 of the total height of the sintered layer [5, p. 65, 68];

- the rate of gas leakage through the sinter layer is 0.35 m/s. These assumptions were made when calculating the dependence of the burning rate of fuel particles on various factors.

The sinter gas specific output subsystem takes into account the flow of carbon into the charge with fuel and limestone, as well as the characteristics of the gas entering the layer.

When developing the formula for the mathematical description of the specific output of the sintering gas, the following assumption was made: the parameters of the air supplied to the layer correspond to atmospheric at a temperature of 25 °C, which is typical for typical sintering conditions.

The bulk density subsystem of the pelletized charge takes into account the characteristics of the charge (chemical and particle size distribution), as well as the fines content in the charge and the ratio of the diameters of small and large particles.

When developing a submodel of the bulk density of the charge, the following assumptions were made:

- the density of the components of the charge is unchanged;

- during pelletizing, the number of relatively large granules increases as a result of rolling a small fraction onto the embryos.

The mathematical model of the movement of the combustion zone in the sintered layer is presented in the form of an expanding network of separate interrelated dependencies (equations), identified as independent submodels.

We set the range of input data for typical sintering conditions:

- the height of the sintered layer does not exceed 500 mm;

- the size of solid fuel (coke breeze) does not exceed 5 mm.

- the chemical composition of the mixture has a number of limitations on the input data on the content of limestone and solid fuel. The limestone content should be in the range from 0 to 25 %, since the nature of the curve of the

temperature change of the air entering the combustion zone with a high content of fluxing additives has not been fully studied. The content of solid fuel (coke breeze) should not exceed 8 %, since some mathematical dependencies expressed in the corresponding submodels will be unfair;

- the density of the components of the charge and air parameters are taken according to the reference data. The density of the charge components (kg/m³): magnetite concentrate 4.7; hematite ore 4.5; coke breeze 1.6; limestone 1.0; dolomitic limestone 1.1; lime 2.0; refund 3.5; manganese ore 4.2.

The adequacy check and adaptation of the model for determining the vertical rate of sintering of the charge was carried out by comparing the simulation results with experimental data obtained in laboratory and industrial studies conducted at the sinter plant of MPP of PJSC “ArcelorMittal Kryvyi Rih” – mining and processing plant of public joint stock company “ArcelorMittal Kryvyi Rih”.

The research was carried out in the laboratory. The ore part of the charge consisted of MPP concentrate (90 %) and Kryvyi Rih agglomeration ore (10 %). For fluxing, a mixture of ordinary and dolomite limestone in a ratio of 3 : 2 and quicklime obtained by firing this mixture of limestones was used. The degree of calcination of limestone was 70 %, the size-3-0 mm. As a solid fuel, a mixture of coke and anthracite block in a ratio of 1 : 1 was used. The content of fuel, return and additional manganese ore in the charge was 4, 18 and 2 %, respectively. The height of the sintered layer was 0.28 m, the charge basicity was 1.3.

The calculation of the numerical methods of the model was carried out using the Microsoft Excel software application. According to the experimental data, the vertical sintering speed for a charge with such parameters is 26 mm/min., and according to the results of calculations using the model it is 26.65 mm/min., which indicates the coincidence of the model properties with the corresponding properties of the simulated object.

The adequacy of individual submodels of the dependence of certain process parameters on various factors was also verified by comparing the calculated and experimental values. So, determining the height of the combustion zone using the appropriate submodel gives adequate characteristic dependencies, shown in Figure 2.

Thus, verification of the adequacy of the model showed the coincidence of the properties of the model and the corresponding properties of the simulated object.

6 Discussion

In order to discuss the simulation results, a study was made of factors affecting the agglomeration rate using the developed model. Using the created model, we studied the dependence of the vertical sintering speed on the solid fuel content at various heights of the sintered layer. The initial parameters of the charge: the basicity of the charge of 1.0; air suction rate 0.35 m/s. Adjustable parameters: solid fuel content in the charge 1-8 %; charge layer height 200-500 mm.

Fig. 2. The dependence the height of the combustion zone from the diameter of the solid fuel at different layer heights the height of the sintered layer, mm: 1 – 150, 2 – 200, 3 – 300, 4 – 400, 5 – 500, 6 – 600

The research results (Fig. 3) show an extreme dependence of the vertical sintering speed on the fuel content (the maximum is in the region of 3.5-3.7 % C), as well as an increase in the vertical sintering speed with a decrease in the layer height, which corresponds to the known laws of the theory of the sintering process.

Fig. 3. The dependence of the vertical sintering speed on the fuel content in the charge at different layer heights, m: ● – 0,2; ■ – 0,3; ▲ – 0,4; × – 0,5.

A model study of the dependence of the vertical sintering rate on the flux content (a mixture of limestone and dolomitic limestone) at different heights of the sintering layer was carried out taking a constant solid fuel content of 4.0 %. Adjustable parameters: charge basicity 0-2.5; charge layer height 200-500 mm.

The research results (Fig. 4) show that limestone is an intensifier of the agglomeration process. With an increase in the basicity of the charge, the sintering rate increases

by 12-14 % (a larger value corresponds to the lowest layer height).

Fig. 4. The dependence of the vertical sintering speed on the basicity of the charge at different layer heights, m: ■ – 0,2; ● – 0,3; ▲ – 0,4; × – 0,5.

The negative effect of limestone supply is to reduce the porosity of the layer of pelletized charge due to an increase in the fraction of the fine fraction in it. The quantitative nature of this dependence is also presented in the corresponding submodel. With an increase in the limestone content in the charge to 25 %, the fraction of fines in the dry charge increases to 85 %. However, this improves the gas permeability of the charge directly during the sintering process. One of the reasons for this phenomenon is obviously a decrease in the content of relatively large granules (more than 10-12 mm) in the pelletized charge, which are prone to destruction in the drying and waterlogging zones during the sintering process.

A positive effect on the gas permeability of the sintered layer with increasing basicity also has a decrease in the optimal moisture content of the charge, since this increases the specific consumption of the heat carrier gas for moisture evaporation, which helps to preserve the strength of the granules.

Another explanation for the increase in the vertical sintering rate is possible, based on calculations of the apparent heat capacity of the charge at different limestone contents. Taking into account the heat that is released during the formation of calcium ferrites, an increase in the proportion of limestone in the charge reduces the maximum temperature in the solid fuel combustion zone, which is accompanied by an increase in gas filtration through the layer.

7 Conclusions

Thus, the performed studies show that the developed mathematical model of the process of moving the combustion zone of solid fuel in the sinter layer of the

sinter charge allows us to study the dependence of the vertical sintering speed on the parameters of the material composition and structural and gas-dynamic characteristics of the sinter charge layer. The obtained numerical description of the process is a local dynamic model, the adequacy of which is confirmed by the results of theoretical and experimental studies. Despite the local nature of the developed model, due to its versatility, it takes into account the main material and structural parameters of the sintering process, which affect the speed of movement of the solid fuel combustion zone, and as such can be considered as element of the universal software package of sintering process model [7].

The scientific novelty of the work consists in the development of a model that for the first time allows us to determine the speed of the agglomeration process without conducting experimental sintering, as well as to investigate the influence of the composition and structural characteristics of the charge on the sintering intensity.

The obtained results create prerequisites for choosing the sintering technology that provides the highest sintering speed and, consequently, the productivity of the sintering machine for specific sintering conditions. This fact is an important factor in ensuring the economic security of sintering production, a condition for its sustainable future.

Abstract. This study displays results of carbothermal reduction researches of titanomagnetite concentrate obtained during complex apatite-titanomagnetite-ilmenite ore dressing. The mineral composition was analyzed and the structural and textural features of the titaniferous ore of Kropivensky deposit and the titanomagnetite concentrate obtained from it were revealed. The mechanism of solid-phase carbothermal the titanomagnetite concentrate reduction is investigated. Temperature-time parameters have been discovered to ensure the formation of both products with the maximum yields of iron and titania from metal and slag-phase during titanomagnetite concentrate reduction. One-stage resource-saving flow chart of titanomagnetite concentrate processing with mass fraction up to 25% TiO₂ is developed.. It allows to obtain two marketable products: granular cast iron (92-96.5% Fe, 3.4-3.7% C, 0.5% V) in 57% yield and titaniferous slag (50-55% TiO₂, up to 7.4% FeO) in 43% yield.

Introduction

Within the framework of the stable metallurgy development program, the team of the Ferrous metals metallurgy and foundry Department of Kryvyi Rih National University scientists deals with the following important tasks: improving the hot-rolled steel plate technology [1] and determining the optimal parameters for the electrical treatment of foundry steels during casting [2]. Another area of research is the development of recommendations for the complex titanium ores involvement in processing. [3]

The rapid development of the metallurgical complex has led to a reducing of quality iron ore reserves amount. In the near future, they will be replaced by complex ores that can meet the needs of ferrous and non-ferrous metallurgy companies. Ukraine has significant complex ore of apatite-titanomagnetite-ilmenite composition reserves. The technologies of their preparation for metallurgical conversion make it possible to obtain basic ilmenite and apatite commodity concentrates and, in addition, titanomagnetite, which can contain 46-52% of Fe and 20-25% of TiO₂.

Titanomagnetite concentrate is not currently processed by existing metallurgical enterprises in Ukraine, but it is a promising raw material for the sustainable development of cast iron, steel, titania (TiO₂) and metallic titanium. The development and implementation of processing technology for this

concentrate will allow the storage of valuable mineral components in the waste heaps. Extant technologies include the use of two-stage processing, which consists of pre-reduction and ore-thermal electric melting, followed by separation into industrial products. These technologies are characterized by high energy consumption and environmental hazards. Therefore, research with the discovering and justification of technical and technological solutions for the processing of titanomagnetite concentrates with a high content of TiO₂ goal is relevant and important for the sustained development of metallurgy.

In research works [4-7], a number of experiments were conducted on solid-phase reduction of titanomagnetite concentrates with mass fraction of Fe 56.5-64.5% and up to 16.7% TiO₂. It has been shown that slag with a wide range of chemical composition from 15.4 to 62.5% of TiO₂ were obtained after their reduction. This is an important basis for studying the iron-containing and titaniferous phases formation mechanism, as well as the allocation of Fe and Ti between them. The analysis of those studies' results does not allow us to completely determine the peculiarities of the structural-phase titanomagnetite transformations at different temperature-time parameters of the carbothermal reduction process. In addition, the titanomagnetite concentrates reduction process with a TiO₂ mass fraction of 20-25% has not been studied.

* Corresponding author: metall.babochko@gmail.com

For carbothermal reduction process, a titanomagnetite concentrate obtained after the apatite-titanomagnetite-ilmenite ore dressing of the Kropivensky deposit was used, having the following composition, mass fraction, %: 45.5 FeO; 23.0 Fe₂O₃; 22.03 TiO₂; 1.5 SiO₂; 1.2 Al₂O₃; 0.26 CaO; 3.4 MgO; 0.42 MnO; 0.516 V₂O₅; 0.04 Cr₂O₃ [8, 9].

Researched ore is low-concentrated, sometimes contain schlier with 1-2 m capacity of high-concentrated varieties. The total content of ore minerals does not exceed 10%. The ore has an apatite-titanomagnetite-ilmenite composition with variations in the ratio of titanomagnetite / ilmenite from 1/1 to 1/5. The amount of apatite is 1-3%. The ores of the deposit are characterized by a Fe/TiO₂ ratio from 1.5 to 4.0.

A defining characteristic of the magmatic process that has led to the titanium ores formation is the fact that minerals are being formed under conditions of constant change in the chemical composition of the residual melt and the individual components in it. In addition, differentiation (separation) of the melt and the arrival of new magma portions can occur. This creates even more complicated crystallization conditions, which are accompanied by the melting of previously formed minerals grains and even their complete melting and digestion. Lowering the temperature in the magmatic cell can lead to the separation of mineral phases already at the solid solution stage, such as ilmenite, as well as Mg – Al and Ti – spinels in magnetite. Sometimes magnetite in pyroxene and others. The peculiarity of all structures of the solid solution decomposition is a very small sized inclusions of one mineral in another (1-2 μm), which in the future, in the industrial ores processing leads to different technological difficulties.

Titanomagnetite is the predominant ore mineral in the ore deposit, in some samples its mass fraction can be up to 13.5% [10,11].

The following research methods were used: microscopy, spectral, structural-textural and X-ray fluorescence analysis.

For roasting and sintering concentrate by method ore coarsening charge, following materials were used: combined bentonite and FERROFORM polymer, flux additive CaF₂, and reductant graphite with minimal mineral content.

Results and discussions

In the study of polished sections under the microscope the titanomagnetite unusualness is noticeable, it is more similar to ilmenite in optical characteristics. If these minerals are separated, in the form of isolated grains, it is difficult to distinguish them. They are easier to distinguish in joint inclusions – by a noticeable reddish tint in the color of titanomagnetite (Fig. 1, a, b). In addition, ilmenite appears to be lighter, which is most likely due to the Fe₂O₃ impurity in its composition.

In some grains of titanomagnetite under the microscope, the lamellar ilmenite inclusions in the form of decomposition structures of a solid solution are easy to identify (Fig. 1, c, d). The partial oxidation and

leaching of the magnetite component of titanomagnetite under the weathering bark on gabbro-peridotites impact seems to present a true picture of the titanomagnetite grains structure and composition. The study of such ore samples using a microscope made it possible to characterize the titanomagnetite under study, to understand its nature and to develop technologies for the mechanical ore dressing and the subsequent heat treatment of titanomagnetite concentrate.

Fig. 1. Theilmenite and titanomagnetite ratio in joint inclusions: a) morphology of titanomagnetite and ilmenite grains; b) idiocrism of ilmenite, apatite and sulfide compared to later titanomagnetite; c) lamellar inclusions of ilmenite in titanomagnetite; d) homogeneous titanomagnetite (lower part of the grain), which fades into decay structures with ilmenite plates (upper part of the grain). 1 – titanomagnetite (creamy with a reddish tint), 2 – ilmenite (white with a grayish tint), 3 – iron sulfides (white), 4 – apatite and silicates (different shades of gray).

Microscopy revealed that the grains of titanomagnetite, separated in space, have almost the same size (from 0.03 mm to 0.6 mm) as ilmenite, and are often with it in the fusion (Fig. 2, a, b, c) [12].

Single grains have a homogeneous (homogeneous) structure. Most often they are an aggregate of two or more mineral phases. They coalesce at a very thin submicron level, being elements of solid solution decomposition structures. Therefore, the term “titanomagnetite” is a fairly conditional term. Separate grains (and essentially aggregates of two or four mineral phases), whose chemical composition is determined by the FeO, TiO₂ and Fe₂O₃ content, are the titanomagnetites of this deposit. They have high magnetic characteristics. These grains are characterized by the different mineral phases' presence: magnetite, ilmenite, and Al-Mg spinel in small quantities, which are formed after the collapse of the solid mortar. The ratio of these phases in titanomagnetite grains is different.

The magnetite forms the basis of the grain matrix into which the lamellar ilmenite or ulvospinel excretions are immersed and the micro-grain “relict-ilmenite”

(Fig. 2). The lamellar isolates of ulvospinel generally have a thickness of up to 2-3 microns. Single titanomagnetite grains have lamellar isolates of ilmenite or ulvospinel up to 8-10 microns in size. At the same time there are grains of titanomagnetite with different saturation structure and size of secretions (plates) of ilmenite or ulvospinel (Fig. 1, c, d and 2, a, b). The orientation of the plates according to the octahedral separation in magnetite is characteristic of titanomagnetite, often with the formation of lattice structures (Fig. 2, a).

Fig. 2. Features of the titanomagnetite grains structure a) ore grain: left – ilmenite, right – lattice structure of titanomagnetite; b) octahedral titanomagnetite crystals with solid solution decomposition structure and relict inclusions of ilmenite; c) ilmenite in the form of free grains, relict inclusions and plates in the structure of the solid solution decomposition in the grain of titanomagnetite; d) lamellar ilmenite, semi-melted relict grains of ilmenite, incorporation of apatite crystals into titanomagnetite. 1 – lattice structure of titanomagnetite, 2 – ilmenite (light cream), 3 – apatite and silicates (different shades of gray).

The micrograin “relict – ilmenite” is often semi-alloyed, sometimes they are solitary, but more often concentrated in groups (Fig. 2, b, c, d). The size of micro-grains inclusions is 0.05 – 0.1 mm. These are micro inclusions its remains “Magnetite” magma beneficiated by titanium. The presence of “relict – ilmenite” micro grain causes a high (up to 25%) content of TiO_2 in titanomagnetite grains [13].

Titanomagnetite is also characterized by the presence of a higher concentration of V than in ilmenite. This is due to the fact that Fe has a close crystal-chemical bond with V, and since ilmenite has a smaller proportion of Fe, the concentration of V in it will be lower.

Based on the study of the morphological structures of apatite-titanomagnetite-ilmenite ore, the classification of titanomagnetite grains is made:

- grains with fine ilmenite in the magnetite matrix ($\text{Fe} - 42.36 \pm 2.18\%$, $\text{Ti} - 14.47 \pm 0.96\%$);
- grains having the structure of uniformly distributed lamellar secretions of ilmenite in the magnetite matrix

($\text{Fe} - 34.25 \pm 1.4\%$, $\text{Ti} - 11.37 \pm 0.37\%$);

- grains having the structure of equally distributed lamellar secretions of ilmenite and separate microgranules of “relict-ilmenite” in the magnetite matrix ($\text{Fe} - 31.24 \pm 1.73\%$, $\text{Ti} - 18.65 \pm 1.08\%$).

Analysis of these types of titanomagnetite concentrate grains confirmed their complex structure and showed that the reduction conditions of this concentrate will be significantly different from the reduction parameters of iron-containing magnetite concentrate.

The calculations show that the magnetite matrix of titanomagnetite grain contains up to 34.6% of Fe, and in the ilmenite particle – up to 15% of Fe. The different structure of the grains and their elemental composition make it necessary to determine the optimal temperature and time parameters for the reduction of the magnetite matrix and the release of ilmenite, which will achieve the maximum extraction of Fe and TiO_2 in the industrial products.

It is established that the obtained coils have satisfactory characteristics for their further reduction: porosity – 30-35%, compressive strength – 1.32 kg/pellet (for dry – 2.7 kg/pellet), reset strength – 4.2 times.

The process of carbothermal reduction of coils with a diameter of 10-14 mm was carried out in the temperature range of 800-1500 °C.

Studies of the pellet's microstructure at different temperature-time parameters of the treatment process showed that the reduction of the titanomagnetite concentrate happened in two temperature-time periods, in which significant physicochemical and structural-phase transformations occur.

In the first period (“low-temperature zone”, 800-1000 °C) there is a physicochemical transformation of iron-containing silicates (olivine and pyroxene) with the formation of magnetite and its subsequent reduction to Fe^0 . At 900 °C, solid-phase changes start in titanomagnetite grains. Around the grains appears a dark border of 10–15 microns thick, characterized by a higher titanium content (Fig. 3, a).

It happens as a result of the restoration of the magnetite matrix of the grain with the formation of Fe^0 in the form of droplets less than 0.1 μm and its diffusive removal beyond the grain boundary (Fig. 3, b).

At 1000 °C in volume of pellets solid-phase changes are accelerating. Up to 1 microns of Fe^0 appear. With increasing the holding time at this temperature up to 40 min, the intensity of both the reduction of the magnetite matrix in titanomagnetite grains up to 0.06 mm and the release of Fe^0 increases. There is an intense formation of a metal sponge (Fig. 3, c, d). In grains of more than 0.06 mm in size, the concentration of which is not more than 20% in the concentrate, solid-phase transformations with separation of Fe do not occur.

In the second thermo-time period (“high-temperature zone”, 1000–1300 °C), the accumulations of Fe^0 continue. Titanomagnetite grains complete the reduction of the magnetite grain matrix. At a temperature of 1200 °C, “relict-ilmenite” and a grid of ilmenite remain in place of the titanomagnetite grains, which are inherited from the structures of decomposition of the solid mortar (Fig. 3, c).

Fig. 3. Structural transformations in coils reduced at 900-1300 °C: 1 – grains of titanomagnetite (cream color); 2 – allocation of metallic iron (white color); 3 – ilmenite mesh; 4 – slag phase (dark gray and gray).

Exposure for 5-40 min at 1300 °C ensures the aggregation of Fe⁰ clusters up to 0.1-0.2 mm, and shutter speed up to 50 min – the appearance of regions of Fe⁰ spherical in diameter up to 2 mm. The slag titanium phase begins to form from the ilmenite mesh. At the endurance of 80 min, the enlargement of Fe⁰ regions to 3.5 mm continues, the content of Ti decreases to 2%, but in them there are significant accumulations and separate inclusions of secretions with the content of Ti up to 31% (Fig. 3, d). The Fe content in the slag phase gradually decreases from 38% to 25%, and the Ti content increases from 23% to 39% (Fig. 3, d) [3].

For maximum extraction of Fe⁰ and TiO₂ into the iron and titanium phase, a complete reduction of the magnetite particle in all grain types is observed, which is observed as a result of holding for 20 min at 1300 °C (Table 1), as well as further raising of the temperature to 1500 °C with holding 5 min. This ensures the reduction of FeO in the ilmenite particle of the grains. The total degree of metallization of the coils thus increases to 94%.

The reduced product (Fig. 4, a) is a shell-shaped porous formation of a slag phase with a wall thickness of 2-3 mm, and a separated iron phase in the form of spherical particles up to 30 mm (Fig. 4, b). The slag phase is mainly composed of thin-needle and thin-fiber aggregates of rutile and anatase with up to several micrometers thickness (Fig. 4, c).

Sometimes, in the slag phase, glass inclusions and single residual semi-melted titanomagnetite ore grains of

0.04 × 0.07 and 0.07 × 0.15 mm with a FeO border 1-3 μm thick are observed around them.

Fig. 4. Reduced product (a), the microstructure (b, c; x200) and the chemical composition (mass, %) Of the products of reduction: 1 – the separation of metallic iron (white color); 2 – slag titanium phase (different shades of gray); 3 – semi-melted grains of titanomagnetite (cream color).

Thus, the parameters of a two-step process for the reduction of titanomagnetite concentrate were determined, which ensure the formation of iron-containing and titaniferous products with maximum extraction of Fe⁰ and TiO₂ in them. These parameters are: I degree – reduction of the magnetite particle with increasing temperature from 800° C to 1300 °C; II degree – restoration of ilmenite particle with increasing temperature from 1300 °C to 1500 °C.

It should be noted that the formation of metal granules from grains of titanomagnetite is a complex process that happens due to the diffusion of Fe⁰ microparticles into the intergranular space with its subsequent enlargement due to autogenesis. The forces of adsorption attraction, which are caused by covalent, ionic, polarizing or intermolecular (dispersion) forces, have a significant effect. But several types of these forces are possible at the same time. As the temperature of the process increases, the formation of liquid metal clusters into a spherical shape continues due to coalescence (coagulation). In order to prevent impediments to the coagulation processes of the iron particles and the inhibition of the process of separation of the metallic and slag titaniferous phases, this phase must be converted to a visco-plastic state.

Table 1. Chemical composition of slag phase at the temperature reduction of during 800-1300 °C temperatures and holding time of 20 and minutes.

Holding time	Series of tests	Mass particles, %				
		Fe	Ti	V	Si	Mn
20 min	1	16.7	37.58	0.58	0.42	2.42
	2	14.4	32.97	0.17	0.85	0.47
Average		15.65±1.5	35.28±2.86	0.38±0.25	0.64±0.27	1.45±1.21
40 min	1	36.61	29.37	0.35	2.13	1.42
	2	42.13	30.68	0.22	1.42	1.81
Average		39.37±3.4	30.03±0.81	0.29±0.08	1.78±0.44	1.62±0.24

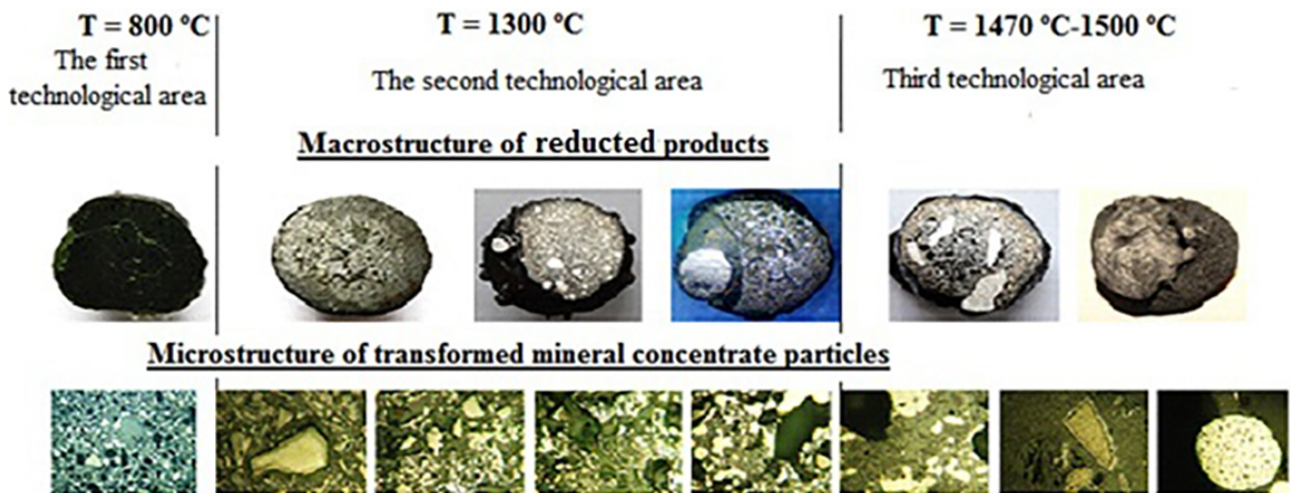

Fig. 5. Chart of structural-phase transformation in the carbothermal reduction of the pelletized titanomagnetite concentrate.

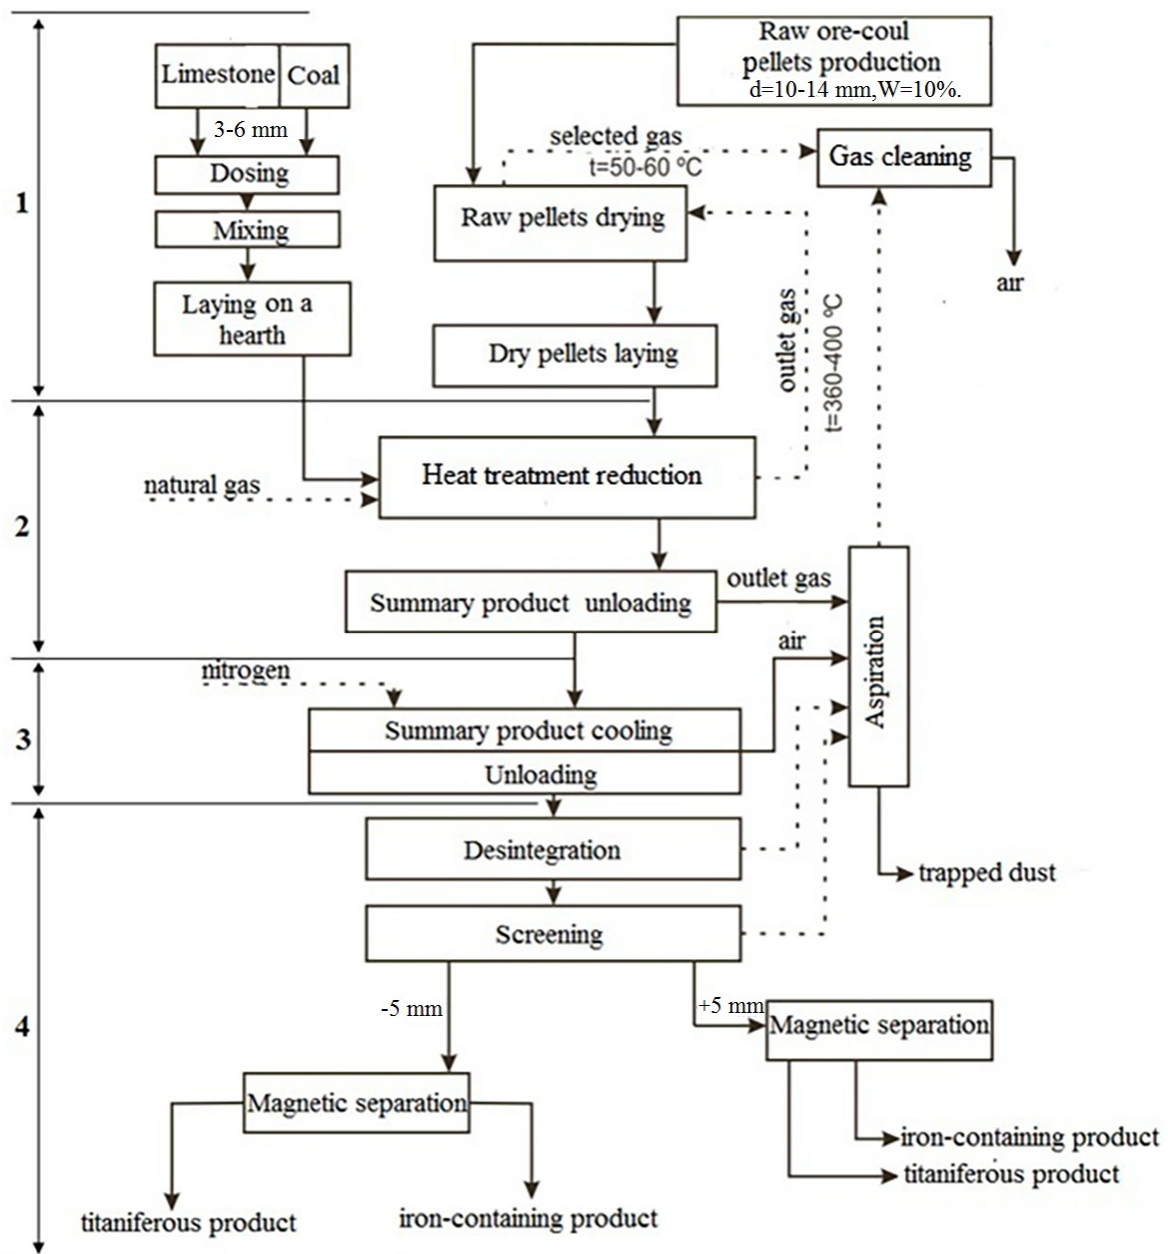

Fig. 6. Flow chart of titanomagnetite concentrate processing.

It is advisable to carry out the process of two-stage reduction with certain technological parameters in a direct reduction furnace with annular hearth, since the final product is not granulated iron, but granular cast iron. This oven has high operational reliability, economy and environment friendliness.

Chart of structural-phase transformation at certain parameters. The carbothermal reduction of the titanomagnetite concentrate in this furnace is shown in Fig. 5.

According to the results of the research, the working area of the furnace is divided into technological sections (Fig. 5):

section I – loading of the material and its heating from 600 °C to a temperature of 800 °C;

section II – heating from a temperature of 800 °C to 1300 °C with a speed of 20 °C/min and holding for 15-20 min – indirect reduction of the magnetite part of the titanomagnetite grain;

section III – heating from a temperature of 1300 °C to 1470-1500 °C at a speed of 50 °C/min and holding for 5 min – direct reduction of residual magnetite and FeO from ilmenite parts of titanomagnetite grains.

The flow chart of titanomagnetite concentrate processing for obtaining marketable products with maximum extraction of Fe⁰ and TiO₂ in them was developed and tested (Fig. 6). This scheme includes the basic production operations: 1 – occlusion of charge materials and their drying, 2 – heating, reduction and melting of coils in a high-temperature unit, 3 – cooling the product; 4 – grinding and dividing of the obtained product into magnetic and non-magnetic fraction.

The yield of the iron-containing fraction was 57% in the form of cast iron granules (92-96.5% Fe; 3.4-3.7% C, 0.5% V), the yield of the slag fraction was 43% in the form of titaniferous slag with 50 -55% TiO₂ and up to 7.4% FeO.

Conclusions

As a result of the research, it was discovered that the structural-phase transformations during the carbothermal reduction of the pelletized titanomagnetite concentrate proceeds by the following scheme: physicochemical and structural transformations of the olivine and pyroxene minerals at 800 °C; the beginning of the magnetite matrix reduction of grain with the iron diffusion into the intergranular space at 900 °C; complete reduction of the magnetite component of grain with the ilmenite mesh and “relict-ilmenite” formation at 1200 °C; the emergence of the titaniferous phase as a result of the ilmenite grid reducing and the “relict-ilmenite” at 1300-1500 °C. The parameters of the two-step reduction process of titanomagnetite concentrate, which provide the formation of iron-containing and titaniferous products with maximum extraction of Fe⁰ and TiO₂ in them, are experimentally discovered. I step – magnetite phase reduction with increasing temperature from 800 °C to 1300 °C and holding for 20 min at a final temperature (it provides complete reduction of the magnetite phase of grain). II step – reduction of ilmenite phase with

increasing temperature from 1300 °C to 1500 °C with holding at a final temperature of 5 min. A one-stage resource-saving flow chart of titanomagnetite concentrate processing with a mass fraction up to 25% TiO₂ has been developed based on carbothermal reduction of pellets in an annular hearth furnace. It allows to obtain two marketable products: granular cast iron (92-96.5% Fe, 3.4-3.7% C, 0.5% V) in 57% yield and titaniferous slag (50-55% TiO₂, up to 7.4% FeO) in 43% yield.

Abstract. The inherently low capacity of the classically used carbon-based anode is one of the major drawbacks hindering the wide application of lithium ion batteries (LIBs) in electric vehicles. Carbon replacement with materials possessing high theoretical capacity, such as germanium (Ge) represents one of the approaches used for ensuring wider LIBs’ implementation. The main disadvantage of the Ge use is its huge volume change during the lithiation / delithiation, causing Ge-based electrodes pulverization, deterioration of the electrochemical properties and resulting in electrodes relatively short life. Usage of Ge based nanomaterials is regarded as powerful tool for overcoming the mentioned drawbacks. This paper reviews and discusses the very recent progress in the preparation and studying the Ge nanoparticles (NPs), Ge nanoalloys and Ge-based nanocomposites as attempts for preparation of advanced anodes for LIBs.

1 Introduction

The lithium-ion batteries are widely used and their application in portable electronics and electric vehicles or hybrid electric vehicles is expected to be increased. LIBs are rechargeable batteries possessing high energy density, low self-discharge and no memory effect. Every LIB (more correctly a battery pack) consists of gathered together electrically connected electrochemical cells and electronics for control and protection. The cell (that is the primary electrochemical unit) contains electrodes, separator, and electrolyte. In the most commercial cells the negative electrode (anode) is made of graphite.

The positive electrode is a lithium-based material. It can be a layered oxide (for example lithium cobalt oxide), a polyanion (like lithium iron phosphate), or a spinel (for instance lithium manganese oxide). The electrolyte usually represents a mixture of organic carbonates, typically ethylene carbonate (EC), diethyl carbonate (DEC), ethyl methyl carbonate (EMC), dimethyl carbonate (DMC), containing lithium complexes, such as lithium hexafluorophosphate (LiPF₆), lithium perchlorate (LiClO₄), lithium tetrafluoroborate (LiBF₄), lithium hexafluoroarsenate monohydrate (LiAsF₆), and lithium triflate (LiCF₃SO₃).

Anode and cathode allow lithium ions (Li⁺) to move in and out of their framework, the Li⁺ insertion process (lithiation) is called intercalation and the Li⁺ extraction (delithiation) one – deintercalation. During the discharge an oxidation reaction proceeds at the anode and positively charged Li⁺ and negatively charged electrons are formed. The Li⁺ move through the electrolyte to the cathode where they are inserted in the cathode material (often forming a lithium compound) with the aid of

electrons that are transported from anode through an external circuit to the cathode. When the cell is being charged, the reverse reaction occurs – the Li⁺ and electrons move back into the negative electrode.

The capacity decrease in LIBs is most often due to the loss of lithium to the solid-electrolyte interphase (SEI) that forms at the negative electrode. Initially, during charging at temperature below 25 °C metallic lithium is produced spontaneously on the electrode surface. Further the lithium reacts with electrolyte to form Li₂O, LiF, Li₂CO₃, and polyolefins. This is due to the fact that the electrolytes typically used in LIBs are not stable at the electrode operating potential during charging and they may decompose. At the beginning, SEI formation increases the electrode resistance to solvent decomposition but the increase in the SEI thickness with time leads to a gradual decrease of the LIB’s capacity.

The commercial graphite exhibits a relatively low theoretical capacity of 372 mAh/g (electrode capacities are compared by using three measures: specific energy or gravimetric capacity (capacity per unit of mass), volumetric capacity (capacity per unit volume), and areal capacity (area-normalized specific capacity)). This fact leads to an intensive search for other materials. Materials forming alloys with Li, such as Si, Ge, Sn are actively researched as alternatives to carbon-based anodes for rechargeable LIBs due to their higher theoretical capacities in comparison to commercial graphite. For example, Ge possesses theoretical specific capacity of 1600 mAh/g (at 4.4 Li⁺ per Ge atom), an electronic conductivity 10⁴ times higher than silicon, and high Li⁺ diffusivity (more than 400 times higher than that in silicon at room temperature) [1].

* Corresponding author: marichim@mgu.bg

The unsatisfying cycle life (due to the volume expansion / contraction during the lithiation / delithiation reaction, causing the formation of cracks, pulverization of the electrodes, destroying the conductive network of the electrode, thus deteriorating the storage capacity of lithium and worsening the cycle performance) appeared as one of the most challenging problems of the recently developed anode materials. Ge particles aggregation during the Li^+ insertion / extraction leads to an increase in the internal resistance and in Li^+ diffusion path resulting in inability of the internal Ge particles to participate in chemical reactions. The final result is capacity loss and more generally – poor electrochemical performance.

The investigations trying to solve the above-mentioned problems are going to the following directions: (a) alloying with the Li-active / inactive materials, (b) preparing nano-structured electrodes, and (c) surface modification by introducing conducting and / or nonconducting buffer components [2].

Application of nanostructured materials is considered a promising approach for bettering the electrochemical properties of electrodes. Nanostructured electrodes possess a very large specific surface area that can increase the contact area between the electrodes and the electrolyte. This big contact area is able to accelerate the exchange of ions and electrons at the electrode / electrolyte interface. Furthermore, owing to their very short internal diffusion paths, the nanoscale materials possess much higher ionic or electronic conductivities compared to their bulk counterparts. In addition, they can also resist to bigger mechanical deformation during charge / discharge cycling. Since Ge possesses high theoretical capacity, good electrical conductivity and fast Li^+ diffusivity, Ge-based nanomaterials have recently attracted considerable attention as LIB electrode materials.

Recently, different nanoscale Ge-based anodes with a variety of morphologies have been developed to raise the electrochemical performances of these anodes and the results are presented in the worldwide literature.

The most comprehensive overview of anodes for LIBs is provided by Hu and co-authors [3]. The paper covers studies carried out till the first quarter of 2016. The paper has extensively reviewed the preparation and the entire characterization of nanoparticles (NPs), nanowires (NWs), and nanotubes (NTs) made of single Ge, Ge alloys with metals (such as Cu, Sn), with semiconductors (such as Si, Se), and germanium chalcogens alloys such as GeS.

Preparation of electrodes based on Ge/carbon nanotubes (CNTs), Ge/graphene, Ge-reduced graphene oxide-CNTs (Ge-RGO-CNTs), Ge-reduced graphene oxide nanofibres (Ge@RGO NFs) aimed at achieving a longer cycling life of the LIBs and their characterization is also presented by the same paper.

A special attention is paid to the preparation and characterization of core-shell structural electrodes because of their high conductivity, excellent stability and the ability to prevent the significant volume changes in the Ge electrode during the charge/discharge process. LIB anodes based on Ge@C core-shell; Ge@Cu core-shell; Ge@C/graphene, Ge@C/RGO, Cu@Ge core-shell

NW; and 3D TiO_2 @Ge core-shell nanorod arrays on carbon textiles are briefly discussed.

Attention is drawn also to LIB anodes made of Ge based nanomaterials (NWs, NPs, and nanorods) that are ternary alloys and their composites (such as $\text{Cu}_3\text{Ge}/\text{Ge}$ NWs, $\text{Cu}_3\text{Ge}/\text{Ge}/\text{graphene aerogel}$), as well as double oxides and their composites (such as CuGeO_3 , $\text{Cu}_3\text{Ge}/\text{GeO}_x/\text{CuGeO}_3$ NWs, CuGeO_3 NWs / graphene composites, $\text{CuGeO}_3/\text{RGO}$ composites, $\text{Ca}_2\text{Ge}_7\text{O}_{16}$ NWs on carbon textiles, $\text{Ca}_2\text{Ge}_7\text{O}_{16}$ NW/ graphene sheet nanocomposite, Zn_2GeO_4 NWs and nanorods, Zn_2GeO_4 -GO nanocomposite, Cd_2GeO_4 NWs, Cd_2GeO_4 NW / CNT and the Cd_2GeO_4 NW/GO/CNT nanocomposite films, PbGeO_3 NWs, SrGe_4O_9 and BaGe_4O_9 NWs).

The results from testing the all above-mentioned materials as anodes in cells for LIBs are also presented.

Additionally, a brief discussion is given on the performance of LIBs electrodes made of germanium oxide (GeO_2) NPs, GeO_2 NPs/RGO composite, and GeO_2 -C fibre composite.

Influence of the LIB's electrolyte type, the discharge current density, the working temperature, the cycling rate¹, the shape and morphology of the Ge-based materials has been presented when it was discussed in the original papers.

For all presented electrodes data are provided on the specific capacity (mAh/g) – initial and after cycling, current density (mA/g) and the number of charge-discharge cycles. However, for comparative purposes, the data presented have to be used cautiously, going to the original papers to check the exact cycling rate and the number of cycles related to the reported specific capacities and current densities.

An other review paper is devoted to the advances in studies on the synthesis, optical properties and applications of germanium nanocrystals, including their use as anodes for LIBs [4]. The paper covers studies carried out in the period 2010-2015 and only two of the papers reviewed in [3] are referred to also in [4]. The author pays special attention to the Ge nanocrystals (NCs) use in anodes for LIBs. The Ge NCs/RGO composite and a composite of Ge NCs encapsulated within carbon nanofibers ((Ge)0D@((CNF)1D) are presented, including means for those composites preparation, their characterization and results from their testing as anodes for LIBs (specific capacity (mAh/g) – initial and after cycling at different rate, and the number of charge-discharge cycles).

Figure 1 presents schematically the major Ge-based nanomaterials studied until 2016 as potential anode (active) materials for LIBs.

Having in mind the importance of developing high-performance LIBs and the exponentially growing studies in the area, we consider that it would be useful for the

¹ A C-rate is a standard unit of the rate at which a battery is discharged with respect to its maximum capacity. A 1C rate denotes that the discharge current will discharge the whole battery in 1 hour. As an example, for a battery with a capacity of 100 Ah, 1C is equal to a discharge current of 100 A, a 5C rate for this battery would be 500 A. (http://web.mit.edu/evt/summary_battery_specifications.pdf)

reader to be supplied with up-to-dated information on the subject.

Fig. 1. Schematic representation of the major Ge-based nanomaterials studied until 2016 as potential anode (active) materials for LIBs

In this mini-review article, we overview the further development in the use of Ge-based nanomaterials and nanocomposites for LIBs' anodes by covering the studies in the recent three years.

2 Recent approaches for preparing germanium based nanomaterials for high-performance anodes for LIBs

The studies aimed at improving the performance of Ge containing LIBs anodes in the recent 3-4 years have continued in the following directions: nano-structured germanium, germanium oxide based materials, germanium alloys based nanomaterials and preparation of electrodes based on Ge and carbon (or its derivatives).

2.1 Nano-structured germanium

A new direction in the synthesis Ge-based nanomaterials for LIBs is proposed that relies on pulsed laser-assisted electrodeposition from ionic liquid at room temperature [5]. The utilized ionic liquid was 1-ethyl-3-methylimidazolium bis (trifluoromethylsulfonyl) imide ([EMIm]Tf2N) that did not require supporting electrolytes as is the case with organic solvents. The laser irradiation allowed for controlling the size, shape, and distribution of nanoparticles since it ensured clustering and vertical growth of Ga nanospheres and further development of Ge nanowires (non-branched and

branched). The pulsed laser irradiation facilitated the direct electrodeposition of Ge nanowires on a copper (Cu) foil.

The characteristics of the produced material were studied utilizing home-made cells. The Ge NW electrode was used to prepare coin-type half cells (2025R size) by applying Li metal as the counter electrode. The separator was a microporous polyethylene (PE) and the electrolyte was 1 mol/L LiPF₆ in EC-DEC mixture. The prepared Ge nanowire anode exhibited an initial discharge capacity of 1646 mAh/g and initial charge capacity of 1278 mAh/g. The large initial discharge capacity and irreversible capacity loss measured were assigned to the irreversible formation of SEI. However, the capacity reversibility was much better in the next cycles and the capacity of 884 mAh/g was retained after 50 cycles at 0.2C, while the coulombic efficiency (CE) was higher than 96%. The capacity decay was less pronounced compared to that observed for Ge nanoparticle film prepared by non laser-assisted electrodeposition.

The studied Ge nanowire electrode showed reversible capacities of 1230, 1160, 1070, 960, and 730 mAh/g at 0.1C, 0.2C, 0.5C, 1C, and 2C, correspondingly. In addition, the capacity returned to 1100 mAh/g when the rate was decreased to 0.1C. These findings show that the properties of pure Ge anodes can be improved by pulsed laser assisted ionic liquid electrodeposition. The improved properties of thus prepared electrode were assigned to the laser-assisted transformation of the amorphous Ge deposits from films in the absence of laser irradiation to polycrystalline structures (nanowires and branched nanowires) under laser irradiation. This structure supplies channels facilitating the transport of Li⁺. The result is higher diffusion rate of Li⁺. The polycrystallinity of the nanostructures also averts pulverization of the electrode materials during LIBs' cycling by facilitating volumetric expansion throughout the entire nanostructure.

Preparation of porous structures is considered an efficient way for mitigating the negative effect of the LIBs' volume expansion and contraction during lithiation and delithiation. In this line, a 3D ordered macroporous (3DOM) nickel (Ni) framework (Ge/3DOM-Ni) was prepared by using drop-coating technique to attach Ge nanoparticles to the Ni framework [6]. Germanium nanoparticles were produced by reduction of germanate ions with NaBH₄, the former were prepared through reaction of GeO₂ with NaOH. Thus prepared Ge nanoparticles were dispersed in ethanol by ultrasonication. The obtained suspension was drop-coated onto the heated 3DOM-Ni framework. The self-supporting porous Ge/3DOM-Ni electrodes were produced by annealing the 3DOM-Ni framework, bearing the Ge nanoparticles, at 500 °C for 2 h in Ar atmosphere.

To study the properties of thus prepared anodes a coin-type half cells (2025R size) were assembled. Microporous PE was used as the separator, Li metal as counter and reference electrode, and 1M LiPF₆ in EC – DEC (1:1 vol.%) as the electrolyte. The discharge-charge study was carried out at a current density of 0.2C (1C is approximately 1600 mA/g) within the potential range of 0.01–2 V (vs. Li⁺/Li). Initially a low CE of

53.3% was recorded, corresponding to the initial discharge and charge capacities of approximately 1869 and 996 mAh/g. This effect is assigned to the SEI layer formation. The discharge and charge capacities for the second cycle were 1053 and 1052 mAh/g, correspondingly, ensuring the CE of approximately 100%. No definite variation was observed in the specific charge capacities of the Ge/3DOM-Ni electrodes in the initial 10 cycles, pointing at good structural stability. After 100 cycles a specific charge capacity of 610 mAh/g was observed while the CE remained c.a. 100%.

The rate performance of the Ge/3DOM-Ni electrode was studied at rates of 0.1C, 0.2C, 0.5C, 1C, 2C, 5C, and 10C. The obtained respective reversible capacities of the Ge/3DOM-Ni electrodes were approximately 1337, 1042.5, 930, 817.5, 685, 460, and 270 mAh/g. The good performance of the Ge/3DOM-Ni electrode is mainly attributed to the 3DOM-Ni framework, since the easily accessible macroporous channels ensure efficient transport pathways for electrolyte and Li^+ and highly conductive framework for electron transport. The high porosity of the prepared electrode (confirmed by SEM observations) helped to avoid the negative effect of the volume enlargement of the Ge nanoparticles at cycling. The work showed that porous Ni frameworks are good supports and current collectors for Ge-based LIBs anodes. The use of polymer binders and conductive substances is avoided, thus the specific capacity is increased.

Recently a study is reported on the effect of mass loading on the areal capacity, capacity retention, and rate performance in high-capacity Ge electrodes for LIBs [7]. The results are of interest, since the application of electrodes with an areal capacity over 3 mAh/cm² meets different obstacles, such as electrode delamination from the current collector, increased resistance – electronic and ionic, substandard electrolyte penetration, and underutilization of the electrode at high current densities. To overcome the problems, a porous Ge was prepared by reducing GeO_2 under hydrogen atmosphere at 450 °C. Further a the slurry was prepared by mixing 70 wt.% of the produced active material with the binder (20 wt.% poly (acrylic acid) and the conductive agent (10 wt.% acetylene black). The electrodes were elaborated by tape casting of the produced slurry.

To study the electrochemical behaviour of the prepared electrodes CR2016 coins cells were fabricated. Metal Li was used as the counter electrode for the half cells and commercial LiCoO_2 electrodes were applied in studies on the full cell cyclic performance. The electrolyte applied consisted of 1M LiPF_6 in mixture of ED, DEC and DMC (1:1:1 by volume).

The electrochemical behaviour of the Ge electrode was studied using galvanostatic charge/discharge process in the range of 0.02 and 1.2 V vs Li/Li^+ . At a current density of 1000 mA/g, 340 stable cycles were achieved and the final specific capacity was approximately 1300 mAh/g for the mass loading of c.a. 1 mg/cm². The slight capacity drop in the initial cycles was assigned to the formation of SEI, as well as to some loss of electrical contact due to the rearrangement of active materials. The increase in the specific capacity at further cycling is

assigned to the electrode activation by the deeper lithiation into the active materials. The first cycle CE was 60%, it increased to 92% for the 2nd cycle, and reached approximately 99% for the 10th cycle.

The electrode cyclic performance was studied (up to 1800 cycles) at the high current density of 5C (i.e. 8 A/g, since 1C = 1600 mA/g) and at the low loading of 0.56 mg/cm². A CE over 99% was achieved starting from the 3rd cycle. This long term cycleability at the high rate was explained by the porous morphology of the Ge electrode that was able to sustain the lithiation induced stress without undergoing pulverization. In addition, the electrode with such morphology provided better electrolyte accessibility and simultaneously ensured shorter Li^+ diffusion lengths.

To evaluate the practical behaviour of the electrode, the electrochemical characteristics of a full cell consisting of Ge anode and lithium cobalt oxide cathode was studied. At a current density of 1 mA/cm² the areal capacity at the end of 180 cycles was 0.68 mAh/cm² at CE of 99.6%.

Transmission electron microscopy (TEM) and selected area electron diffraction were used to study the electrode morphology before and after cycling and the phase transformation. The results indicated that the electrode stability resulted from the ability of the individual grains to keep the electrical contacts between them, even at big changes in the volume due to the lithiation.

Macroporous (MP) Ge@TiO_2 composite, consisting of nanoscale Ge network skeleton wrapped with TiO_2 particles was prepared by dealloying of $\text{Ge}_{4.5}\text{Ti}_{0.5}\text{Al}_{95}$ alloy via its immersion in 0.01 mol/L NaOH solutions at 25 °C for 4 h [8]. During the selective dissolution of Al, Ge atoms were brought together and formed three dimensional (3D) network nanostructure with high porosity. Meanwhile Ti atoms were oxidized and further (by a spontaneous aggregation) formed TiO_2 particles layer that covered the porous Ge surface.

In order to study the lithium storage performances of the prepared Ge@TiO_2 material, CR2032 coin-type cells were fabricated where Ge@TiO_2 -based material served as the anode active substance. Anodes with pure Ge as active material were also prepared for comparison. The other materials included in the slurry used to prepare anodes, besides the active materials, were Super P, and sodium alginate. Cu foil was used as current collector. The counter electrode was a lithium foil, and the separator – a microporous membrane. The electrolyte was 1 mol/L LiPF_6 dissolved in the mixture of EMC, DMC and EC (1:1:1 – a volume ratio) with an addition of 3 v.% vinylene carbonate (VC) that acts as film forming additive.

Studies on the cycling performances and CEs of Ge@TiO_2 anode and pure Ge anode were carried out at current density of 400 mA/g. The Ge@TiO_2 electrode provided a reversible capacity of 963 mAh/g after 100 cycles while the capacity of pure Ge was 418 mAh/g, thus suggesting the more stable lithium storage performances of the Ge@TiO_2 material.

The cycling performances of MP Ge@TiO_2 and pure Ge anodes at current density of 3200 mA/g were also studied. Ge@TiO_2 maintained reversible capacity of

716.7 mAh/g after 300 cycles, while the capacity of pure Ge electrode at the 300th cycle was 126.4 mAh/g. TEM images showed that the structure of pure Ge underwent serious fracture and collapse after cycling while the Ge/TiO₂ material preserved its original porous network architecture.

The rate performances of MP Ge@TiO₂ and pure Ge electrodes were studied, as well. The Ge@TiO₂ electrode exhibited specific discharge capacities of 1182.2, 1040.4, 955.3, 820.0, and 774.8 mAh/g at the current densities of 160, 400, 800, 1600 and 3200 mA/g, correspondingly. The pure Ge showed lower capacity at all current densities and a discharge capacity of only 134.6 mAh/g at 3200 mA/g. When the current density was back to 160 mA/g (after it was 3200 mA/g) the specific capacity for Ge@TiO₂ returned to 1036.5 mAh/g indicating very good rate performance.

The excellent characteristics of the prepared material were explained by its structure. The 3D macroporous network with its channels accelerates the movement of electrons and ions during lithiation/delithiation process. The robust TiO₂ layer ensures mechanical strength and prevents the direct contact between Ge and electrolytes, thus hindering the continuous increase of SEI which causes the capacity decrease.

2.2 Germanium oxide based nanomaterials

Due to its high theoretical capacity of 2152 mAh/g, in the case that it reversibly stores 8.4 Li⁺, GeO₂ is considered as an encouraging anode material for LIBs [9]. In addition, GeO₂ is cheaper than pure Ge. However, its fast implementation in LIBs is hindered by the GeO₂ poor electrical conductivity and the very big volume changes during the charge/discharge process, resulting in the degradation (pulverization) of the electrode material, unstable SEI and as a result poor performance. In an attempt to obtain novel GeO₂-based anode materials with enhanced performance, preparation of porous GeO₂ nanoparticles through thermal decomposition of (Hbipy)₂[Ge(C₂O₄)₃]·2H₂O in air atmosphere has been proposed [9]. The idea was to use the ability of porous structures to relax the mechanical strain resulting from the volume expansion during cyclic process, as well as their large surface area facilitating electrode-electrolyte interface, and thin walls ensuring fast diffusion of Li⁺.

The prepared porous GeO₂ nanoparticles possessed an average size of 200 nm, pores of 4 nm, BET surface area of 74.0 m²/g and total pore volume of 0.208 cm³/g.

When used as LIB's anode the materials exhibited a discharge capacity of 2578.8 mAh/g at current density of 100 mA/g. Even at current density of 2 A/g, the reversible specific capacity was 184.2 mAh/g. After the high-rate measurements, the specific reversible capacity was 727 mAh/g when the current density was set back to 100 mA/g. This finding points at good electrochemical reversibility and structure stability.

A comparison of commercial GeO₂ and the synthesized porous GeO₂ nanoparticles pointed at the superiority of the latter. After 100 cycles at 100 mA/g, the porous GeO₂ possessed a reversible capacity of 581.9

mAh/g for Li⁺ storage, while that of the commercial GeO₂ was 256.5 mAh/g. The good performance of the prepared material is assigned to the synergism of nanoscale, porous structure and low crystalline structures formed during the synthesis.

One-pot environmentally friendly synthesis of amorphous Ge oxide-carbon (GeO_x-C) hollow composite has been proposed by using citric acid (CA) as reductant of the germanium ions obtained by dissolving GeO₂ in NH₄OH [10]. The amount of the added reductant influenced the thickness of the resulting hollow structure, but the hollows' size of the GeO_x materials was not changed. Under the optimum ratio of CA to GeO₂ 13-16 nm shells were formed and this material showed the best electrochemical performance.

The LiB anode prepared using this material exhibited a capacity of 930 mAh/g after 100 cycles at rate of 0.3C, while the CE was 99.9%.

The cycling stability of the GeO_x-C hollow composite was studied by gradually applying C-rate from 0.1C to 10C. At that, the specific capacity of the sample slowly decreased from 956 to 612 mAh/g. Nevertheless, when 0.5 C was applied after 10C, the reversible capacity come back to 935 mAh/g showing a very good performance. The repetitive fast cycles charge/discharge' carried out at rate of 2C showed that after 400 cycles the reversible capacity was 757 mAh/g, (approximately 90% retention compared to the second cycle) pointing at good cycling stability.

It has been found that during the lithiation/delithiation process the thickness of the GeO_x-C hollow composite electrode changed by approximately 12%, while the thickness of an electrode prepared from commercial GeO₂ changed by up to 150%. The HRTEM analysis of the GeO_x-C hollow composite showed well preserved hollow structure and uniform distribution of Ge and O atoms even after 400 cycles.

The enhanced electrochemical performance of the GeO_x-C hollow composite was assigned to the synergistic effect of the hollow structure with optimized thickness of the shells, amorphous nature, and the presence of conductive carbon. The composite shell layers supplied a surface for formation of stable SEI layer by avoiding the direct contact between the electrolyte and the anode. Availability of an internal void space ensured free expansion of the anode material without increasing the volume of the entire electrode. All these features allowed for an effective accommodation of volume change and facilitated transport of electrons during charge/discharge process.

2.3 Germanium alloys-based nanomaterials

Germanium alloying represents one of the ways for mitigating/avoiding the structural pulverization and loss of electrical conduction paths between the active materials and current collector in LIBs' anodes. In line with these efforts free standing non-carbon electrodes were prepared by mixing Ge and Cu nanowires [11]. The electrodes were tested as anodes for LIBs. Half-cells (of CR2032 type) were prepared using as working electrode

the produced free standing NW fabric, Li metal foil was the counter electrode. The electrolyte was 1 M LiPF₆ in 3:7 (v/v) fluoroethylene carbonate/dimethyl carbonate (FEC/DMC) and it was loaded on a microporous PE separator. The material prepared under optimum conditions exhibited initial charge and discharge capacities of 1348 mAh/g and 1107 mAh/g corresponding to the CE of 82.1%. Its capacity retention was 80.3% after 50 cycles.

High-resolution SEM and TEM images of the electrodes before and after 100 cycles showed that before cycling Ge nanowires waved with each other into the fabric structure. The X-ray spectroscopy (EDS) of the contact point revealed that the atomic ratio of Cu to Ge was 3:2, which proved the formation of copper germanide. After cycling, the nanowire composites were coated by a uniform SEI layer.

The free standing NW fabric electrodes possess the following advantages for application in LIBs: (i) The elaborated electrode structure needs neither a metal foil current collector nor polymer binders in the production process. As a result, the whole electrode is considerably lighter than conventional electrodes made by slurry coating on metal foils; (ii) The existence of the raw material in the form of wires supplies many intersections between NWs (like 3D interconnectivity) leading to an accelerated electron transport; (iii) The space between the NWs can alleviate the volume changes during alloying and dealloying process and improve the electrolyte penetration leading to easier Li⁺ diffusion in the electrode.

The Cu content and the annealing temperature were found as the two main factors determining the electrochemical performance of the free standing NW anode electrodes.

Use of core-shell array nanostructures as LIBs' anodes is able to significantly improve the electrochemical performance, especially the high-rate capability. Cobalt-germanium core-shell nanowire array anode (Co-Ge CNA) was synthesized by template-free approach applying direct deposition of a Ge layer on the surface of the preliminary synthesized Co NW arrays [12]. RF-sputtering method was used.

To study the performance of the produced material as anode for LIBs, 2025 coin-type half cells were assembled with a metallic lithium foil as the counter electrode, 1M solution of LiPF₆ in EC / DMC (1:1 by volume) as electrolyte and polypropylene micro-porous film as a separator.

At a current density of 320 mA/g the initial discharge and charge capacities of Co-Ge CNA were 1994.8 and 1441.4 mAh/g correspondingly, resulting in an initial Coulombic efficiency (ICE) of 72.3%. The irreversible capacity loss in the first cycle is assigned to the SEI formation. In the further cycles the Co-Ge CNA anode exhibited practically constant capacity and it was 1535 mAh/g after 100 cycles.

The rate performance of Co-Ge CNA electrodes was studied under different current rates in the range of 0.2C – 5C. The discharge capacities of 1493, 1482, 1467, 1357 and 1239 mAh/g were recorded at 0.2, 0.5, 1, 2 and 5C (= 8000 mA/g), correspondingly. However, when

again a current of 0.2C was applied, the Co-Ge CNA electrodes showed a capacity of ~1446 mAh/g and a stable cycling performance. The good rate performance is assigned to the core-shell array nanostructures that are able to provide vigorous mechanical support, fast electron transport, and improved contact to the current collector.

2.4 Nanocomposites of germanium and carbon-based materials

Composites consisting of Ge NPs and carbon-based materials continue to be considered among the most promising materials for preparation of LIBs' anodes, since carbon coating on Ge particles acts as a buffer layer effectively limiting volume expansion and aggregation of Ge NPs. In comparison with amorphous carbon coating, the ordered mesoporous carbon (OMC) in addition to providing large surface area, uniform pore size and good conductivity, can be used as a matrix that contains electroactive material, exercising a confining effect and maintaining the integral structure. Combining Ge nanoparticles with the advantages of ordered mesoporous structure is considered as a plausible strategy for the synthesis of high-capacity, long-cycle life electrode materials.

A composite consisting of Ge NPs embedded in spherical ordered mesoporous carbon (S-OMC/Ge) was prepared by impregnating the ammonium salt of Ge in the pores of OMC, followed by high temperature pyrolysis and H₂ reduction [13].

The electrochemical performance of the synthesized composite as an active anode material was tested by preparing CR 2032 coin cells. The anode contained the active material, acetylene black, and binder polyvinylidene fluoride (PVDF) at a mass ratio of 75:15:10, the current collector was Cu foil. A lithium plate was the counter electrode, and the electrolyte was 1.0M LiPF₆ in EC – DEC at ratio 1:1 vol.%.

The cycling behaviour of S-OMC/Ge based electrodes as well as of electrodes based on pure spherical OMC (S-OMC) and pure Ge materials were studied in 160 cycles at the current density of 100 mA/g. The capacity of S-OMC sample was 643 mAh/g after 160 cycles. The capacity of Ge electrode was 173 mAh/g after 3 cycles, showing a rather poor cycling performance. The composite S-OMC/Ge sample exhibited a stable circulation in the 160 cycles, with capacity of 996 mAh/g.

The rate performance of the S-OMC/Ge electrode was evaluated by applying different current densities. The measured reversible discharge capacities were 1025, 934, 807 and 681 mAh/g at applied current densities of 100, 200, 500 and 1000 mA/g, correspondingly. When the applied current density was returned to 100 mA/g, the reversible capacity was stabilized at 890 mAh/g after 60 cycles. The reversible capacities measured under the same conditions for S-OMC and pure Ge samples were much worse. The cycle stability of S-OMC/Ge electrode was studied also at high current density of 1 A/g. The

electrode maintained a reversible capacity of 530 mAh/g after 200 cycles and the CE was stable, at 99.2%.

The proposed explanation of the high capacity of S-OMC/Ge composite was by the complete structure formed by Ge particles (that possess a high theoretical capacity) even distribution in the mesoporous carbon.

It was found that the content of Ge had an effect on the performance of S-OMC/Ge composites. The low Ge content was not enough to ensure the impact of the Ge high theoretical capacity, while use excessive Ge lead to Ge agglomeration and blocking of the mesoporous carbon pores, which affected the overall performance of S-OMC/Ge composite.

The good performance of the prepared composite is assigned to the synergistic effect between the support of spherical OMC and the high capacity provided by dispersed Ge particles. The spherical ordered mesoporous carbon supplies channels able to alleviate the volume changes during the lithiation / delithiation cycling and ensures high electrical conductivity.

Decreasing the aggregation of Ge NPs occurring during electrodes' cycling represents another direction for improving the properties of Ge NPs based anodes for LIBs. NPs' anchoring on conductive substrates, such as graphene (Gr), CNTs, and RGO or NPs encapsulation in hollow carbon active material is accepted as the problem's solution. These carbon materials prevent large volumetric expansion thus ensuring long-term stability and high electrical conductivity resulting in high power of the batteries.

The reactive sites of nitrogen doped single walled carbon nanohorns (N-SWCNHs) were utilized by favourably growing of germanium nanocrystals (Ge NCs) onto their conical tips by applying oleylamine as a reducing agent [14]. The prepared Ge@N-SWCNHs composite was studied as an active anode material for LIBs. For this purpose CR2032 coin cells were elaborated with Li chips as reference and counter electrode, the separator was dried glass fibers membrane and the working electrode was Ge@N-SWCNHs composite, casted on a copper foil. The slurry casted on the foil consisted of 70 wt.% Ge@N-SWCNHs composite (containing 70 wt.% Ge), 20% Super-P carbon and 10% PVDF in N-methyl-2-pyrrolidone (NMP). The electrolyte was 1 M LiPF₆ dissolved in 1:1 mixture of EC and DMC with 5 v.% of VC as an additive.

The capacity of Ge@N-SWCNHs composite based electrode after 5 cycles stabilized at 1435 mAh/g while for an electrode based on Ge NCs as an active material the capacity was 1046 mAh/g. The higher capacities obtained for Ge@N-SWCNHs composites were assigned to the lower activation energies permitting entire utilization of active material. The capacity retention of electrodes based on Ge NCs and Ge@NSWCNHs composites was tested for over 100 cycles. Pristine Ge NCs and Ge@N-SWCNHs composites showed stable discharge capacities of 811 and 1285 mAh/g after 100 cycles, correspondingly. The main part of the delithiation capacity in Ge@N-SWCNHs composite was lost during the initial 10 cycles (6%) while the loss was 2.5% for the remaining 90 cycles. The CE of Ge@N-

SWCNHs composite after 20th cycle was higher than 95%, and for the 80th cycle it was practically 100%.

The rate behaviour of Ge@SWCNHs composite was studied at various charge / discharge rates and compared with the behaviour of Ge NCs and of pristine NSWCNHs under the same conditions. At rates of 0.1C, 0.4C, 0.8C, 1C, 2C and 5C the capacity of Ge@N-SWCNHs composite based electrodes was 1420, 1193, 935, 866, 611, 366 mAh/g, correspondingly. The capacity of Ge NCs based electrodes was 908, 762, 599, 462, and 271 mAh/g at 0.1C, 0.4C, 1C, 2C and 5C correspondingly, while the capacity of pristine NSWCNHs was 48, 36, 26, 15 and 9 mAh/g at 0.2C, 0.4C, 0.6C, 0.8C and 1C respectively. When after applying the highest discharge rate, it was returned to 0.1C, the capacity of Ge NCs based electrode was 850 mAh/g, while the Ge@SWCNHs based electrode recovered its original capacity of 1413 mAh/g.

The high storage capacities and the excellent rate behaviour of Ge@N-SWCNHs were assigned to the very good contact between Ge NCs and N-SWCNHs leading to high utilization of the active material. The preferential growth of Ge NCs on the tips of N-SWCNHs averts the NCs aggregation after many charge/discharge cycles.

Production of N-SWCNHs is relatively cheap and scalable and this makes the synthesized composite a promising candidate for LIBs anodes.

A layered germanium phosphide (GeP₃) – carbon black nanocomposite was prepared by high-power ball-milling technique [15]. The nanocomposite was tested as active material for LIBs anode. A button-type electrochemical half cell was assembled where Li metal was applied as the counter and reference electrodes, the separator was Celgard 2400 membrane, and electrolyte was 1 M LiPF₆ dissolved in EC – DEC (1:1 by volume), containing 5% fluorethylene. The electrode exhibited a capacity of 1450 mAh/g after 30 cycles at rate of 100 mA/g. At high current (1900 mA/g) the capacity was 860 mAh/g. The CE was in the range 87 – 93% after 100 cycles. The observed good electrochemical and cycling performances were assigned to the presence of very small GeP₃ nanocrystallites (3–5 nm) in the amorphous C matrix and to the created short Li⁺ ion diffusion paths.

Recently Ge coating for a 3D porous carbon on the surface of Ni foam has been prepared by ionic liquid electrodeposition followed by annealing [16]. Thus a 3DVoid/Ge@C composite has been produced. The material has been tested as a LIB anode. At current densities of 0.1, 0.2, 0.5, 1, and 2 A/g, the electrode has shown a reversible specific capacity of 1592.9, 1054.9, 921.3, 771.4, and 471.2 mAh/g, correspondingly. The good performance of the prepared material has been ascribed to (a) the elasticity of the carbon sheet that facilitates the contact with Ge nanoparticles and protects pathways for the Li-ions transport and (b) the created 3D micro-nano void structure that decreases the damage from large volume changes during the intercalation and deintercalation process of Li⁺ ions.

Three-dimensional nitrogen-doped graphene foam (NGF) has been prepared that contained interconnected pores and encapsulated Ge quantum dots. The obtained material was covered with polydimethylsiloxane to

produce yolk-shell nanoarchitecture [17]. The material performance was tested by preparing two-electrode CR2025-type coin cells. The separator was porous polypropylene film, lithium foil was used as the counter electrode and 1M solution of LiPF_6 in the mixture EC – DMC – DEC (at volumetric ratio of 1:1:1) was used as an electrolyte. Thus prepared nanocomposite (Ge-QD@NG/NGF/PDMS) showed a reversible capacity of 1220 mAh/g at current of 1600 mA/g, preserved for 1000 cycles. The material exhibited high rate capability of more than 800 mAh/g at current of 64 A/g and 200 cycles. The averaged coulombic efficiency was 99.7% for the studied 1000 cycles. The excellent behavior of the prepared nanocomposite is assigned to the creation of internal void space that ensured better relieving the volume expansion during lithiation. In addition, the N-doped graphene outer shell decreased significantly the exfoliation, pulverisation and aggregation of Ge. The elaborated material is suitable for preparing flexible electrodes.

In an attempt to overcome the negative effect of volume changes during the charging/discharging and the aggregation of Ge particles, a core-shell structured germanium@carbon (Ge@C) NPs were homogeneously anchored on the RGO nanosheets to obtain Ge@C/RGO hybrid [18]. Initially Ge NPs were prepared by a mechanochemical reaction between GeO_2 and Mg powders. Further, Ge NPs were coated with polydopamine films, thus core-shell structured germanium@polydopamine (Ge@PDA) composite was prepared. The next step was the Ge@PDA anchoring on the graphite oxide (GO) making use of the dopamine strong adhesion, followed by calcination to form the Ge@C/RGO hybrids.

The electrochemical behavior of the prepared composite was studied using CR2025 coin-type cells in which working electrode consisted of active material (namely Ge@C/RGO, as well as Ge@C – for comparison), Super P, and lithium polyacrylate at weight ratio of 8:1:1, mixed with deionized water to form homogeneous slurry. Further, Cu foil, serving as a current collector, was coated with the slurry, cast in disks and dried. Li metal was used for counter and reference electrodes, and glass fiber for separator. The electrolyte was 1 M LiPF_6 dissolved in EC – DMC (1:1 by volume) with and addition of 5 wt.% fluoride ethylene carbonate (FEC).

Initially charge and discharge specific capacities were 1692.3 and 1258.5 mAh/g at C/10 (the current density of 1C rate was 1600 mA/g), corresponding to an ICE of 74.4%. This low ICE was assigned to decomposition of electrolyte and SEI formation. The initial discharge and charge capacity of the Ge@C, under the same conditions, were 1495.3 and 1252.1 mAh/g, correspondingly. The higher ICE of the Ge@C compared to the Ge@C/RGO was explained by the higher specific surface area of the latter leading to more surface side reactions and thicker SEI layers. After the second cycle, the CE of Ge@C/RGO electrode reached over 98% and kept at that value for up to 600 cycles.

The reversible capacity of Ge@C/RGO electrode after 600 cycles at discharge rate of 2C was 1074.4

mAh/g, which is 96.5% of the capacity at the 2nd cycle at 2C. For comparison, the reversible capacity of the Ge@C electrode after 600 cycles at 2C was 362.6 mAh/g indicating that only amorphous carbon layers cannot ensure stable long-term cycling performance.

Results from SEM and TEM analyses showed that after 600 discharging / charging cycles the Ge@C electrode suffers from significant pulverization and most of the active materials have lost contact with the current collector. Under the same conditions the Ge@C/RGO based electrode kept its surface morphology and structural stability. This is assigned to the high elasticity of RGO which was able to buffer the stress generated during the lithiation / delithiation of Ge.

The rate capability of Ge@C/RGO and Ge@C electrodes was studied at different current densities. At the rates of 5C, 10C, 15C, and 20C the Ge@C/RGO electrode exhibited reversible capacities of 1319.0, 1104.1, 879.4, and 711.6 mAh/g respectively. Under the same current densities, the Ge@C electrode reversible capacities were 988.9, 511.0, 293.1 and 204.3 mAh/g, respectively. When the rate was decreased to 0.2C the both electrodes recovered high capacity. After 200 cycles of lithiation/delithiation, no significant drop of capacity was observed at rates from 1C to 10C. The specific capacity of Ge@C/RGO electrode after 200 cycles decreased to 436 mAh/g at rate of 20C. However, this is still higher than the theoretical capacity of graphite anode (372 mAh/g).

The excellent rate performance of the Ge@C/RGO electrode is assigned to the double carbon matrix composed of amorphous carbon and RGO nanosheets. The carbon layers ensure conductive pathways for diffusion of electrons and Li^+ . The homogeneous and continuous carbon layers in the core-shell structured Ge@C composite alleviate the large volume changes of Ge during lithiation / delithiation and improve the conductivity of Ge electrode. The uniform anchoring of the core-shell structured Ge@C particles onto the surface of RGO decreases the agglomeration of Ge@C composites and betters the active materials' utilization. The highly flexible RGO nanosheets decrease the stress resulting from the multiple volume changes and enhance the structural stability of electrode during cycling. In addition, Gr nanosheets and carbon shells create a hybrid conductive matrix, which improves the electronic conductivity and minimizes the volume change of Ge.

Similarly, a double-layered protective structure was synthesized in which the hollow cubic Ge@C hybrids were evenly dispersed on RGO sheets, thus forming Ge@C-RGO composite [19]. To prepare the composite Ge-bearing precursor ($\text{NH}_4\text{H}_3\text{Ge}_2\text{O}_6$) was dopamine-coated and further subjected to carbothermal reduction processes to obtain a Ge@C composite where the carbon is N-doped. Further, the cubic Ge@C was dispersed on the RGO. The RGO along with the carbon layer formed a double carbon layer structure protecting Ge particles.

The electrochemical properties of the as-prepared material were studied using CR2032 coin-type cells. The Ge@C-RGO composite was applied as an active material. It was mixed with conductive carbon black and the binder (PVDF) at a mass ratio of 80:10:10, and

dissolved in NMP to prepare a suspension, cast on a Cu foil (current collector). Thus prepared system was used as an anode, Li metal was the counter electrode and the electrolyte was 1.0M LiPF₆ in EC – DEC (1:1 by volume) and 5 wt.% FEC. For comparative purposes, cells using Ge@C or Ge as active anode material were also prepared and studied.

It was found that the discharge capacities of Ge@C-RGO, Ge@C and Ge electrodes at 100 mA/g for 200 cycles were 1183, 567 and 202 mAh/g, correspondingly. The reversible capacity of Ge@C-RGO based electrode at current of 1 A/g for 200 cycles was 710 mAh/g, and the CE reached 99.30%.

The rate capability was studied at specific currents of 100, 200, 500 and 1000 mA/g. The capacities delivered by Ge@C-RGO were 999, 796, 718, and 664 mAh/g correspondingly, while the Ge@C electrode exhibited capacities of 589, 540, 461 and 418 mAh/g under the same conditions. When the specific current returned back to 100 mA/g, the capacities were 991 and 576 mAh/g for Ge@C-RGO and Ge@C respectively, indicating good reversibility of the both electrodes. At the same time, the pure Ge electrode showed a continuous decline in capacity at each current rate, indicating its poor electrochemical stability.

The outstanding electrochemical performance of the Ge@C-RGO based electrode is assigned to the formation of a double-carbon layer protective structure in which the hollow cubic Ge@C hybrids are evenly dispersed on the graphene sheets. The connected carbon shells, as a support structure, keep the shape of the material, alleviating the changes during the cycling, and the Ge@C core-shell structure ensures space for the volume expansion of Ge particles. RGO as a supporting substrate ensures good dispersion and fixation of Ge@C hybrids and with its large-area and high-flexibility buffers the stress caused by volume changes during charging / discharging. The N-doped carbon shell and the graphene network speed-up the transport of Li⁺. The dispersed small Ge nanoparticles shorten the Li⁺ transport path. The both effects contribute to the improved overall conductivity of Ge@C-RGO electrode.

Chen and coauthors reported in situ synthesis of Ge/RGO composites using GeO₂ as Ge source and NaBH₄ as reductant. The process was assisted by a cationic polymer – poly(diallyldimethylammonium chloride) [20]. In this synthesis GeO₃²⁻ anions were adsorbed on cationic polymer-modified graphene oxide sheets by means of an electrostatic interaction. Further, in-situ reduction was carried out leading to the formation of ultrafine Ge nanoparticles (ca. 5 nm) on RGO sheets thus creating uniform sandwich-like structure.

The prepared composite was studied as an active material for LIB, using two-electrode CR2032-type coin cells. Besides the prepared composite, the working electrodes contained conductive agent (acetylene black) and binder carboxymethyl cellulose sodium at weight ratio of 8:1:1. The mixture was dispersed in deionized water and thus formed homogeneous slurry was uniformly coated onto pure Cu foil (serving as current collector), dried and cut into disks used as the working electrodes. Lithium foil was applied as both reference

and counter electrodes. The electrolyte was 1.0M LiPF₆ dissolved in EC – DMC (1:1 by volume) containing 5 wt. % FEC. A full Li-ion cell was also prepared with a cathode, based on commercial LiFePO₄. The LiFePO₄ electrode was made by mixing 80 wt % of LiFePO₄, 10 wt% of acetylene black and 10 wt % of PVDF in NMP. Further, the slurry was spread on an Al foil and dried. Before fabricating the full cell, the Ge/RGO anode was pre-lithiated by placing it in direct contact with a lithium foil in the presence of the cell electrolyte.

It was found that the amount of used RGO influences the electrochemical behavior of the Ge/RGO composite. For the composite with the optimal RGO content the initial charge and discharge specific capacities were 2100 and 1184 mAh/g respectively, resulting in an ICE of 56.4%. The relatively low ICE was assigned to the formation of SEI films. The CE increased to ca. 95.0% at the 3rd cycle, and after 5th cycle became above 99.0% and remained at that value after the 100 cycles at current density of 0.2 A/g.

After 100 cycles the Ge/RGO-based electrode exhibited discharge capacity of approximately 960 mAh/g at 0.2 A/g, while the specific capacity of the prepared for comparative purposes pristine Ge-based electrode was 503 mAh/g after 100 cycles. The improved specific capacity of Ge/RGO-based electrode was explained with the high electrical conductivity and large specific surface area of the RGO matrix.

The rate performance was studied at different current densities. The specific capacities of Ge/RGO based electrode at 0.1, 0.2, 0.4, 0.8, 1, 2 and 5 A/g were 1290, 1194, 1112, 1036, 985, 877 and 631 mAh/g, correspondingly, while (for comparison) the specific capacity of pure Ge was 141 mAh/g at 5 A/g. When the current density of Ge/RGO based electrode was returned back to 0.2 A/g, the reversible capacity recovered to 1177 mAh/g.

The long-term cycling behavior of the Ge/RGO based electrode with the optimal RGO content was assessed at a current density of 1 A/g. The initial discharge capacity was 940 mAh/g, and it was 705 mAh/g after 350 cycles. Even at a high discharge rate of 5 A/g the reversible capacity of the Ge/RGO based electrode was 480 mAh/g after 250 cycles.

Furthermore, the coin-type full cell with the Ge/RGO composite as anode and commercial LiFePO₄ as cathode (at 85 mA/g) delivered an initial charge capacity of 149 mAh/g and discharge capacity of 131 mAh/g, which corresponds to the ICE of 87.9%.

The full cell still possessed a good cycling stability with a specific capacity of 120 mAh/g after 100 cycles at 0.5C. The Ge/RGO//LiFePO₄ full cell showed reversible capacities of 156, 152, 134, 115, 95, 62, 41 and 16 mAh/g at 0.1C, 0.2C, 0.5C, 1C, 2C, 5C, 10C and 15C, correspondingly. When, after the high current discharge, the rate was returned back to 0.2C, the capacity measured was 151 mAh/g. These findings point at the applicability of the Ge/RGO composite as anode in commercial LIBs.

The outstanding electrochemical performance of Ge/RGO composite is assigned to the elaborated nanostructure and to the resulting synergistic effect

between Ge NPs and RGO sheets. The two-dimensional structure and large surface area of the RGO facilitates the uniform dispersion of Ge NPs in RGO matrix, prevents their agglomeration and ensures more active sites for lithium storage. The Ge/RGO composite supplies enough void space to buffer the volume change of Ge and maintain high structural stability during cycling. RGO (when in optimal concentrations) with its high electrical conductivity promotes the electron transport. Its large area ensures better contact with the electrolyte and shortens the transport distance of Li^+ ions thus contributing to the superior rate capability.

Very recently germanene-reduced graphene oxide GeCH_3/RGO nanocomposites have been synthesized and studies as anode materials for LIBs by using home-made 2032 cells [21]. The counter electrode was lithium metal, the separator – Celgard 3500 membrane and the electrolyte – 1 M LiPF_6 dissolved in an EC – DEC – DMC mixture (at 1: 1: 1 in volume) with 2% FEC. The results revealed that the reversible capacity of the material prepared with 30 wt% RGO content (the optimum composition) used as anode was 1195 mAh/g after 5 cycles, and even after 100 cycles it was 1058 mAh/g showing a stable work. The CE was 98%. Even after 500 cycles, the capacities of the material with optimal composition were 439 and 288 mAh/g at current densities of 0.5 A/g and 1 A/g correspondingly, and the respective CE were 98.58% and 99.31%.

Only several months ago a material based on mixed Ge oxide and RGO has been presented [22]. The $\text{CuGeO}_3/\text{RGO}$ nanocomposite makes use of high capacity possessed by CuGeO_3 and stable framework created by the RGO. Thus prepared composite was tested as anode active material for LIBs electrodes. The electrode was made of 80 wt% $\text{CuGeO}_3/\text{RGO}$, 10 wt% conductive acetylene black and 10 wt% binder (PVDF). CR2032-type coin half cells were prepared. The counter electrode was metallic Li and the electrolyte consisted of LiPF_6 dissolved in EC – DEC (at ratio 1:1) with addition of 5 vol% of FEC. It has been found that composite $\text{CuGeO}_3/\text{RGO}$ containing 30 wt% GO exhibits very good electrochemical performance. It possessed a reversible capacity of 909 mAh/g and high CE of 91.49% at the current density of 100 mA/g after 200 cycles. The specific capacities of the prepared composite were 709.4 mAh/g, 609.7 mAh/g and 523.4 mAh/g when it was cycled successively at 200 mA/g, 500 mA/g and 1000 mA/g. At restoration of the current density to 100 mA/g, the capacity recovered to 747.6 mAh/g. The good electrochemical characteristics of the $\text{CuGeO}_3/\text{RGO}$ composite were assigned to the combined effect of the crystalline CuGeO_3 nanorods and RGO sheets framework. The CuGeO_3 nanorods ensure direct transport tunnels for lithium ions, while the RGO sheets supply a stable conductive network having large specific surface area for even dispersion of the CuGeO_3 . In addition, the RGO skeleton restricts the excess volume expansion of CuGeO_3 , thus preventing the pulverization of the electrode during the lithiation/delithiation process.

A brief summary of the studies carried out in the recent 3–4 years on Ge-based nanomaterials preparation

and testing as anode materials for LIBs is presented in Table 1.

Table 1. Brief summary of the recent 3-4 years studies on Ge-based nanomaterials for LIBs anodes.

Material	Capacity, mAh/g	Current density, mA/g	Charge-discharge cycles demonstrated	Ref.
Ge NWs	884	320	50	5
Ge/3DOM-Ni	610	320	100	6
Porous Ge	649 (1300)	8000 (1000)	1800 (340)	7
Ge@TiO ₂ composite	963 (717)	400 (3200)	100 (300)	8
GeO ₂ NPs	582	100	100	9
GeO _x -C composite	930 (757)	630 (4200)	100 (400)	10
Ge NW/ Cu NW composite	889	1300	50	11
Co-Ge core-shell NW array	1535 (1239)	320 (8000)	100 (45)	12
S-OMC/ Ge	996 (530)	100 (1000)	160 (200)	13
Ge@N-SWCNHs composite	1285 (866)	160 (1600)	100	14
GeP ₃ -C black composite	860 (1450)	1900 (100)	100 (30)	15
3DVoid/Ge@C	990 (1300)	100 (100)	100 (10)	16
Ge-QD@ NG/NGF/PDMS	1220 (800)	1600 (64000)	1000 (200)	17
Ge@C/ RGO hybrid	1074.4	3200	600	18
Ge@C-RGO hybrid	1183 (710)	100 (1000)	200 (200)	19
Ge/RGO composite	960 (705 and 631)	200 (1000 and 5000)	100 (350)	20
GeCH ₃ / RGO composite	1058 (439)	200 (500)	100 (500)	21
CuGeO ₃ /RGO composite	909 (523)	100 (1000)	200 (40)	22

3 Conclusions and outlook

As a conclusion it can be said that Ge NPs, Ge nanoalloys and Ge-based nanocomposites have been and are being widely studied for their ability to serve as advanced anodes in LIBs. These materials allow overcoming the problems related to volume expansion / contraction during the lithiation / delithiation reaction, while ensuring high reversible capacity and high rate under the applied test conditions.

However, studies on the cycling performance of the electrodes, based on the developed materials, seldom reach the cycles of the commercially used batteries. Further investigations in this direction are needed, with higher number of charge / discharge cycles.

Most of the cells assembled with the developed anodes resemble primary cells, the studies using as counter-electrode materials applied in real LIBs are very scarce. Studies of whole cells where the developed

materials are working with cathodes based on commercially used materials are highly needed.

Efforts must be continued to find the conditions for convenient production of large quantities of nanomaterials for the preparation and testing of larger batteries, rather than individual electrochemical cells.

Finally, we can say that Ga-based nanomaterials are promising active matter for advanced anodes for LIBs but still much work is required for their implementation in the commercial batteries.

In addition, since the sodium ions cannot intercalate into graphite in a reversible manner, the Ge-based nanomaterials deserve more attention as eventual anodes for sodium-ion battery.

Abstract. Higher efficiency of bulked cargo transportation along international transport corridors can be achieved with a resource-saving tank container described in the study. A characteristic feature of a tank container is the use of circle pipes as the carrying elements of the frame. In order to decrease impact loads between fittings of the tank container and fitting stops of the flat wagon at shunting impacts, the authors suggest filling fittings with viscous or viscoelastic materials of dumping or anticorrosive properties. The study also deals with modelling dynamic loading for the suggested tank container. The accelerations obtained were considered in strength calculations for a tank container as components of the dynamic loading. It was determined that the maximum equivalent loads did not exceed the admissible loads. The research will promote designing new-generation tank containers of improved technical, economical and ecological properties, and improve the working efficiency of combined transportation.

1 Introduction

Higher efficiency of bulked cargo transportation along international transport corridors has necessitated introduction of specialized transport means.

At present oil products are transported by tank wagons and tank containers. And it should be mentioned that recent years have witnessed a clear tendency to transfer part of bulked cargo transported from tank wagons to tank containers due to the mobility of the latter. And in recent years transportation of bulked cargo by tank containers is already estimated at the level of 18% annually out of the total bulked cargo turnover and this rate is going to increase.

Therefore, on-time delivery of oil products needs new-generation tank containers. Some characteristic operational features should be taken into account as early as at the designing stage, particularly the structural loading for different means of transport.

One of the most difficult transportation in terms of power load on the carrying structure is transportation of tank containers by rail flat cars. It is taken that at shunting impacts of flat cars loaded with tank containers the rear stop of an automatic coupling is under a force of 3.5 MN [1-3]. It is considered that the tank container sustains an acceleration of 4.0 g. However, with displacements between fitting stops and fittings the acceleration value can considerably increase. It can harm tank containers in operation and require an unscheduled repair. Therefore, while designing tank containers, it is of primary importance to guarantee their constructional adaption to

certain operational conditions and compliance with the strength and durability requirements

2 Analysis of recent researches

At present, problems of improved carrying structures of vehicles have been considered by many engineers and designers in Ukraine and other countries. However, a further development of technical, economical and operational characteristics of rail transport means requires an extensive search for new engineering solutions [4-7].

Thus, study [8] deals with transfer of a heat flow through the carrying structure of a container. It describes simulation of a heat flow through the multilayer plastic support.

The results of optimization of the carrying structure of a tank container are given in [9]. The study confirms the need to design and implement tank containers as transport means. An improved tank container for transporting light oils was designed.

Tests on metal and composite containers under low temperatures are described in [10]. The study identifies some types of containers advisable for transporting certain types of cargo with consideration of low ambient temperatures.

It should be mentioned that the studies under examination do not consider problems of designing resource-saving tank containers.

The results of the research into the stressed state of an ISO tank container by the finite element method with

ABAQUS software suite are given in [11]. The calculation was made under the static loading according to ISO 1496-3. The objective of the calculation was to define deflections of the frame angles and vertical deflections of the reservoir.

An improved structure of the support platform on the tank wagon for fluid cargo is presented in [12]. The strength calculation was made by the finite element method in Lira software.

However, the studies examined do not pose the problem of optimization of the carrying structures of tank containers to minimize the material capacity.

Considering the analysis of literature resources, we can conclude that, by far, the problems of designing resource-saving tank containers are not sufficiently highlighted.

The purpose of the article. The purpose of the article is to highlight characteristics of modelling dynamic loads on tank containers with frame of circular pipes and structurally improved fittings.

3 Results and discussion

In order to decrease the material capacity of a tank container the authors suggest optimization with the minimal material capacity criterion. A TK25 tank container manufactured by VAT Zarechinskiy Plant of Chemical Machine Building (ISO: 1CC) was taken as a basic structure (Fig. 1).

Fig. 1. A 1CC tank container

The tank container consisted of a frame (of rectangular cross-section pipes) and a tank; it was fixed on the flat wagon with corner fittings.

A prospective approach in achieving the objective is implementation of profiles, as the carrying elements of the frame, which provide lower metal structural capacity and meet the strength requirements. An analysis of prospective profiles for car building industry, and the experience gained by other machine building industries confirmed the importance of applying circular section pipes as the carrying frame elements [13].

The authors suggest replacing rectangular pipes for circular pipes as the elements of the carrying structure of a tank container.

The vertical pipe diameter was chosen on the basis of geometrical features of the fitting ($D = 152$ mm). The variation was made by changing the width of the wall S of

the pipe (3 – 5.5 mm). The inner diameter of the pipes changed within a range from 146.5 to 149 mm.

The basic sizes, static characteristics and mass of circular section pipes calculated are given in Table 1.

Table 1. The sizes, static characteristics and mass of a one meter long pipe.

Sizes of a pipe, mm		Cross-section area F , cm ²	Static characteristics for axes x and y		Mass of a one meter long pipe M , kg
Outer diameter, D	Wall width, S		Inertia moment of the section, cm ⁴	Modulus of section, cm ³	
152	3.0	14.04	389.87	51.30	11.02
	3.2	14.96	414.21	54.50	11.74
	3.5	16.33	450.35	59.26	12.82
	3.8	17.69	486.04	63.95	13.89
	4.0	18.60	509.59	67.05	14.60
	4.5	20.85	567.61	74.69	16.37
	5.0	23.09	624.43	82.16	18.13
	5.5	25.31	680.06	89.48	19.87

In order to optimize the tank container structure, spatial meta-models were built in SolidWorks software [14], the strength calculation was made with the finite element method [15-18]. The results of the research conducted are given in Table 2.

Table 2. The results of the strength calculation for the spatial models

Outer diameter D , mm	Wall width, mm	Stresses, MPa	Mass, kg	Deformations
152	3.0	318.32	1055.61	$1.701 \cdot 10^{-3}$
	3.2	316.466	1061.69	$1.726 \cdot 10^{-3}$
	3.5	315.482	1070.77	$1.758 \cdot 10^{-3}$
	3.8	314.525	1057.39	$1.790 \cdot 10^{-3}$
	4.0	313.639	1063.38	$1.858 \cdot 10^{-3}$
	4.5	311.555	1078.33	$1.927 \cdot 10^{-3}$
	5.0	311.664	1093.17	$1.948 \cdot 10^{-3}$
	5.5	310.8	1093.17	$1.983 \cdot 10^{-3}$
	5.5 ¹	316.374	1075.17	$1.868 \cdot 10^{-3}$

¹ it is taken that the pipe has cross section along the whole vertical post for the tank container

To obtain the optimal frame structure (optimal structural geometric parameters of pipe sections to be used), the optimization research was made in the

following order: it was determined that optimization be made by the minimal material capacity criterion (m) with meeting the strength requirements (without exceeding the admissible stress values σ); on the basis of structural features, the limits at which variable values could change, i.e. the outer diameter of the pipe (D) and the wall width (S) were determined; it was determined that mathematical models of parametric variations (m , σ , l) were described with two-factor generalized mathematical models which were defined through nine experiments based on the corresponding spatial computer models; and the mathematical models were determined, on the basis of which an additional schedule was built and optimal geometrical parameters of pipes were defined.

At the first stage, the decision was taken to use a circular pipe along the whole height of the vertical post of the tank container. The results of the strength calculation demonstrated that stresses in the contact area between the support and the vertical post did not exceed the admissible values for the steel grade of the metal structure of the tank container. Therefore, while building a spatial computer model of the tank container it was considered that the vertical post of circular section was located on the special superstructure (Fig. 2) in the form of a truncated pyramid. In order to decrease the impact loads between the fittings of the container and the fitting stops of the flat wagon under shunting impacts, when the impact loads exceeded the friction force between the horizontal planes of the fittings and fitting stops, the authors filled the fitting stops with elastic (Fig. 3, a) or viscoelastic (Fig. 3, b) materials of dumping or anti-corrosion properties.

Fig. 2. The spatial model of an improved tank container.

Using the factor values obtained (m , σ , l), the authors approximated them in the form of second-order polynomials:

$$Y = f(x_{t_1}, x_{t_2}, x_{t_3}, x_{t_a}) = a_0 + a_1x_{t_1} + a_2x_{t_2} + a_3x_{t_3} + a_4x_{t_a} + a_{11}x_{t_1}^2 + a_{11}x_{t_1}^2 + a_{22}x_{t_2}^2 + a_{33}x_{t_3}^2 + a_{44}x_{t_a}^2 + a_{12}x_{t_1}x_{t_2} + a_{13}x_{t_1}x_{t_3} + a_{14}x_{t_1}x_{t_a} + a_{23}x_{t_2}x_{t_3} + a_{24}x_{t_2}x_{t_a} + a_{34}x_{t_3}x_{t_a}, \quad (1)$$

where Y – the controlled value, x_{t_a} – the control parameters, a_i – the coefficients of a generalized mathematical model, the numeric values of which were defined through solving an equation system with the data obtained.

Generalized mathematical models and an additional schedule for the optimal pipe parameters of the tank container's frame were developed in a software suite.

The generalized mathematical models obtained have the following form:

$$m = -70130 + 924.3D + 542.416S - 3D^2 + 2.048S^2 - 3.6DS, \quad (2)$$

$$s = 22383.3 - 286.18D - 181.77S + 0.928858D^2 + 1.1853S^2 + 1.1146DS, \quad (3)$$

$$l = -0.4537 + 0.00591D + 0.0038S - 1.916D^2 - 0.000023S^2 - 0.00002DS, \quad (4)$$

where D – the outer diameter of the pipe, mm, S – the pipe wall width, mm, m – the structure mass, kg, l – the deformations in the structure, σ – the stresses in the structure, MPa.

Fig. 3. The fittings of the tank container: (a) with viscous linkage, (b) with viscoelastic linkage.

The mathematic model verification (2 – 4) was made by the mean square error value [19, 20]:

$$\sigma = \sqrt{\frac{\sum_{j=1}^{m-k} (y_j - y_{jp})^2}{m-k}}, \quad (5)$$

where k – the number of coefficients a_i of the generalized mathematical model; m – the number of mathematic modes.

The calculations conducted confirmed the efficiency of the generalized mathematical models obtained [21-23]. And the mean square error value did not exceed 3%.

In order to decrease the impact loads between fittings of the container and fitting stops of the flat wagon under shunting impacts, when the dynamic load P_d exceeds the friction force F_{FR} between horizontal planes of fittings and fitting stops, the authors suggest installing viscous or viscoelastic elements in the fittings of the container.

In order to define the dynamic loading of the container in shunting impacts considering the improvements, a mathematical model (6) was built; the model took into account displacements of the container placed on the flat wagon.

$$\begin{cases} M_{FC}^{gw} \cdot \ddot{q}_1 = P_l - \sum_{i=1}^n (F_{FR} \cdot \text{sign}(\dot{q}_1 - \dot{q}_2) + \beta_v (\dot{q}_1 - \dot{q}_2)), \\ M_C \cdot \ddot{q}_2 = \sum_{i=1}^n (F_{FR} \cdot \text{sign}(\dot{q}_1 - \dot{q}_2) + \beta_v (\dot{q}_1 - \dot{q}_2) + \\ + M_M \cdot l \cdot \ddot{q}_3), \\ I_m \cdot \ddot{q}_3 = M_M \cdot l \cdot \ddot{q}_2 - g \cdot M_M \cdot l \cdot q_3, \end{cases} \quad (6)$$

where M_{FC}^{gw} – the gross weight of a flat wagon; P_l – the value of longitudinal force on the automatic coupling; F_{FR} – the friction force between fitting stops and fittings; M_C – the tank container mass; β_v – the viscous resistance coefficient in the container's fittings; M_M – the mass of the pendulum imitating displacements of bulked cargo in the tank container; l – the length of the pendulum suspension; I_m – the inertia moment of the pendulum; q_1, q_2, q_3 – the coordinates indicating displacements of flat wagon, tank container and bulked cargo, respectively, relative to the longitudinal axis.

At the given viscous resistance in the container's fittings, the acceleration was approximately 40 m/sec² (≈ 4 g) and did not exceed the normalized value [24].

Besides, the total viscous resistance to displacements of one tank container should be within a range from 9 to 54 kN·sec/m.

At viscoelastic linkage between fittings and fitting stops, the mathematical model has the form:

$$\begin{cases} M_{FC}^{gw} \cdot \ddot{q}_1 = P_l - \sum_{i=1}^n (F_{FR} \cdot \text{sign}(\dot{q}_1 - \dot{q}_2) + C_v (q_1 - q_2) + \\ + \beta_v (\dot{q}_1 - \dot{q}_2)), \\ M_C \cdot \ddot{q}_2 = \sum_{i=1}^n (F_{FR} \cdot \text{sign}(\dot{q}_1 - \dot{q}_2) + C_v (q_1 - q_2) + \\ + \beta_v (\dot{q}_1 - \dot{q}_2) + M_M \cdot l \cdot \ddot{q}_3), \\ I_m \cdot \ddot{q}_3 = M_M \cdot l \cdot \ddot{q}_2 - g \cdot M_M \cdot l \cdot q_3, \end{cases} \quad (7)$$

where C_v – the rigidity of the elastic elements in the tank container's fittings.

The rigidity of an elastic element was taken 480 kN/m, and the viscous resistance coefficient – 30 kN·sec/m. The maximum acceleration was about 40 m/sec² (≈ 4 g) and did not exceed the normalized value.

The acceleration values obtained were considered in strength calculations for the tank container.

The strength calculation was made with the finite element method in SolidWorks software suite [25-27]. When designing the finite element model of the tank container, isoparametrical tetrahedrons were used; the optimal number of them was determined with the grapho-analytical method.

The basic characteristics of the finite-element model for the optimized tank container are given in Table 3.

Table 3. The basic characteristics of the finite-element method of the optimized tank container

Parameter	Value
The number of Jacobian points	4
The number of units	376555
The number of elements	1162350
The maximum size of an element, mm	20
The minimum size of an element, mm	4
The minimum number of elements in a circle	10
Ratio of an element size expansion	1.7
Maximum side ratio	177.52
Percent of elements with a side ratio less than 3	36.7
Percent of elements with a side ratio more than 10	0.939

While designing the strength model for the tank container, it was considered that the structure was effected by vertical static loads P_v^{st} , pressure of bulked cargo P_p , longitudinal pressure on the bottom P_l , horizontal pressure on the fitting stop P_{hp} conditioned by the force P_n , and vertical load on the fitting P_v conditioned by P_v^{st} (Fig. 4).

Fig. 4. The design diagram of the tank container.

The tank container was fixed in the areas where the flat wagon rested on fitting stops. The 09G2C steel was used as a construction material.

The maximum equivalent stresses were 294.1 MPa (Fig. 5, 6). The maximum displacements were concentrated in the area of the access door and accounted for 7.24 mm (Fig. 7, 8), the maximum deformations were $2.79 \cdot 10^{-3}$ (Fig. 9, 10).

Fig. 5. Stressed state of the tank container.

Thus, the research conducted confirmed the efficiency of decisions taken during designing the tank container.

Fig. 6. Stressed state of the tank container (bottom view).
